Rank, Redundancy and Linear Dependence

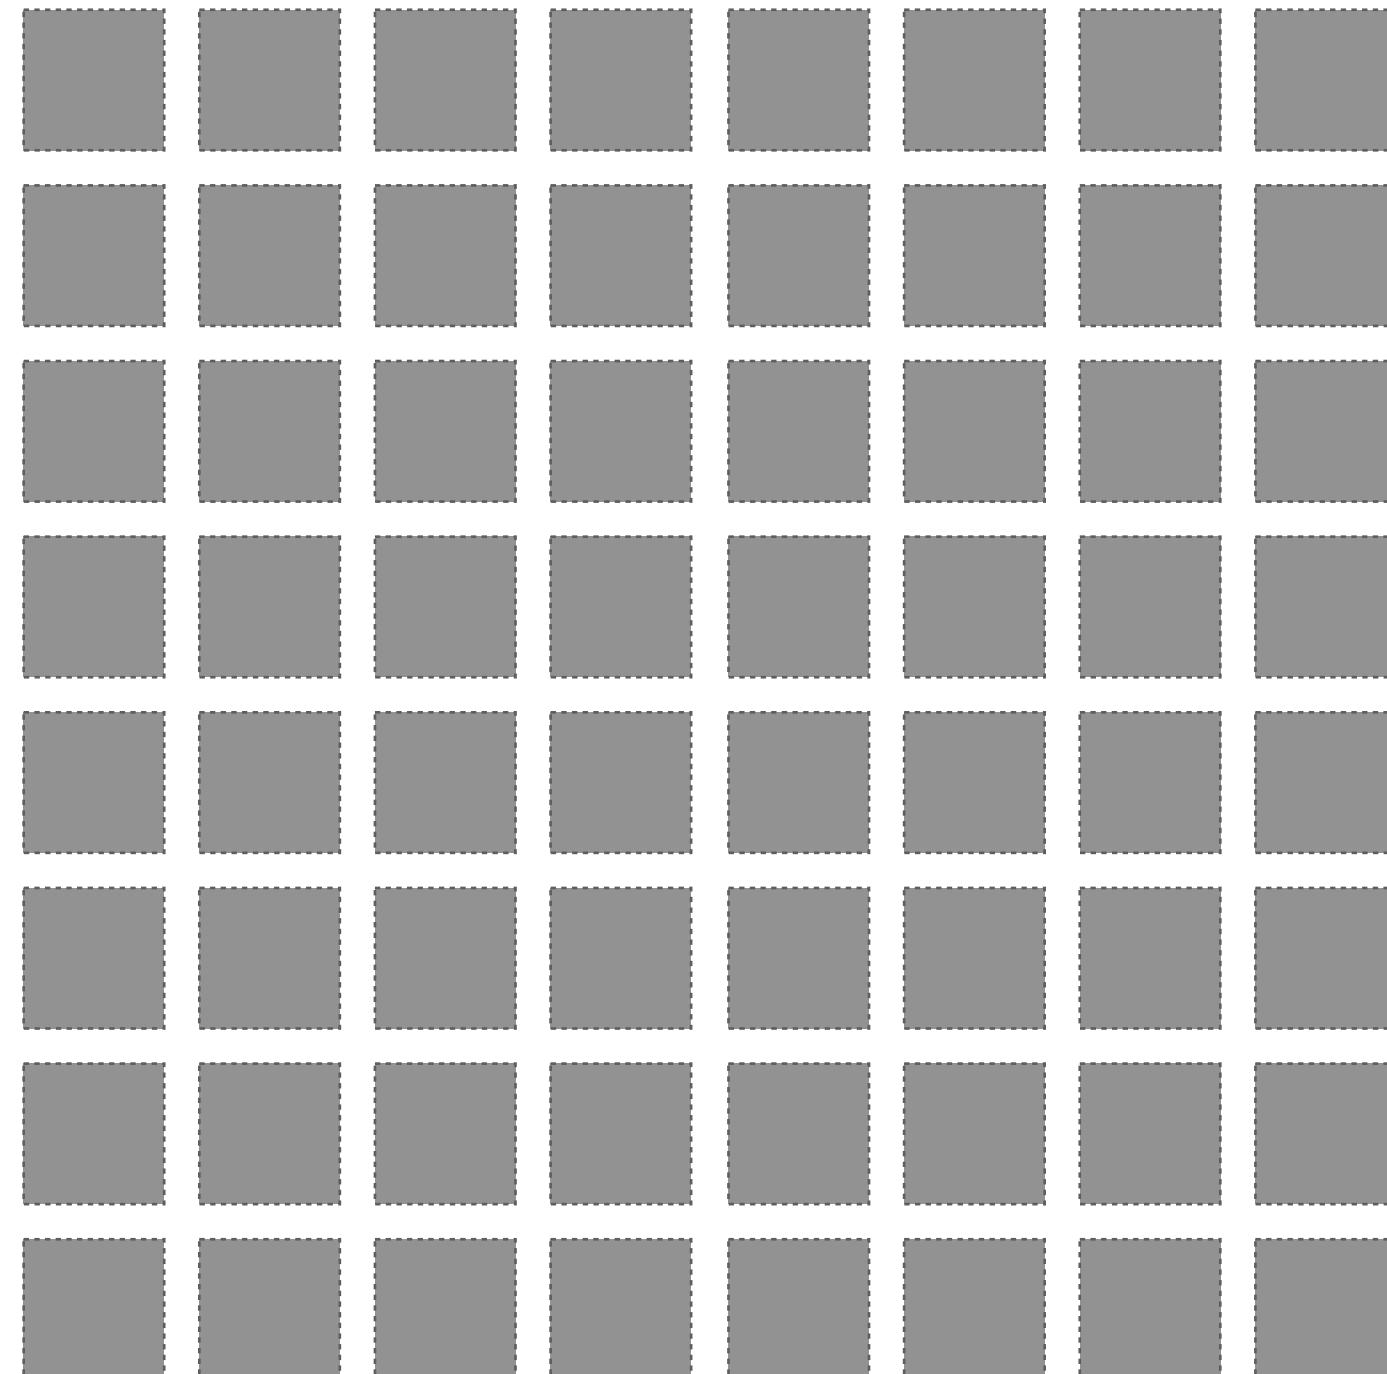

- The **rank** of a matrix is:
 - the number of non-zero singular values
 - the number of linearly independent rows and columns in the data
 - the dimension of the row and column spaces

Rank, Redundancy and Linear Dependence

- When a matrix is **low-rank**, we can say that:
 - there is information shared across entries of the matrix
 - the rows and columns of the matrix are not linearly independent
 - the rows and columns of the matrix are correlated
 - the rows and column vectors lie in low-dimensional subspaces
 - the matrix is redundant

Examples of signals formed by linear combinations of 2 vectors

Connection to Sparsity

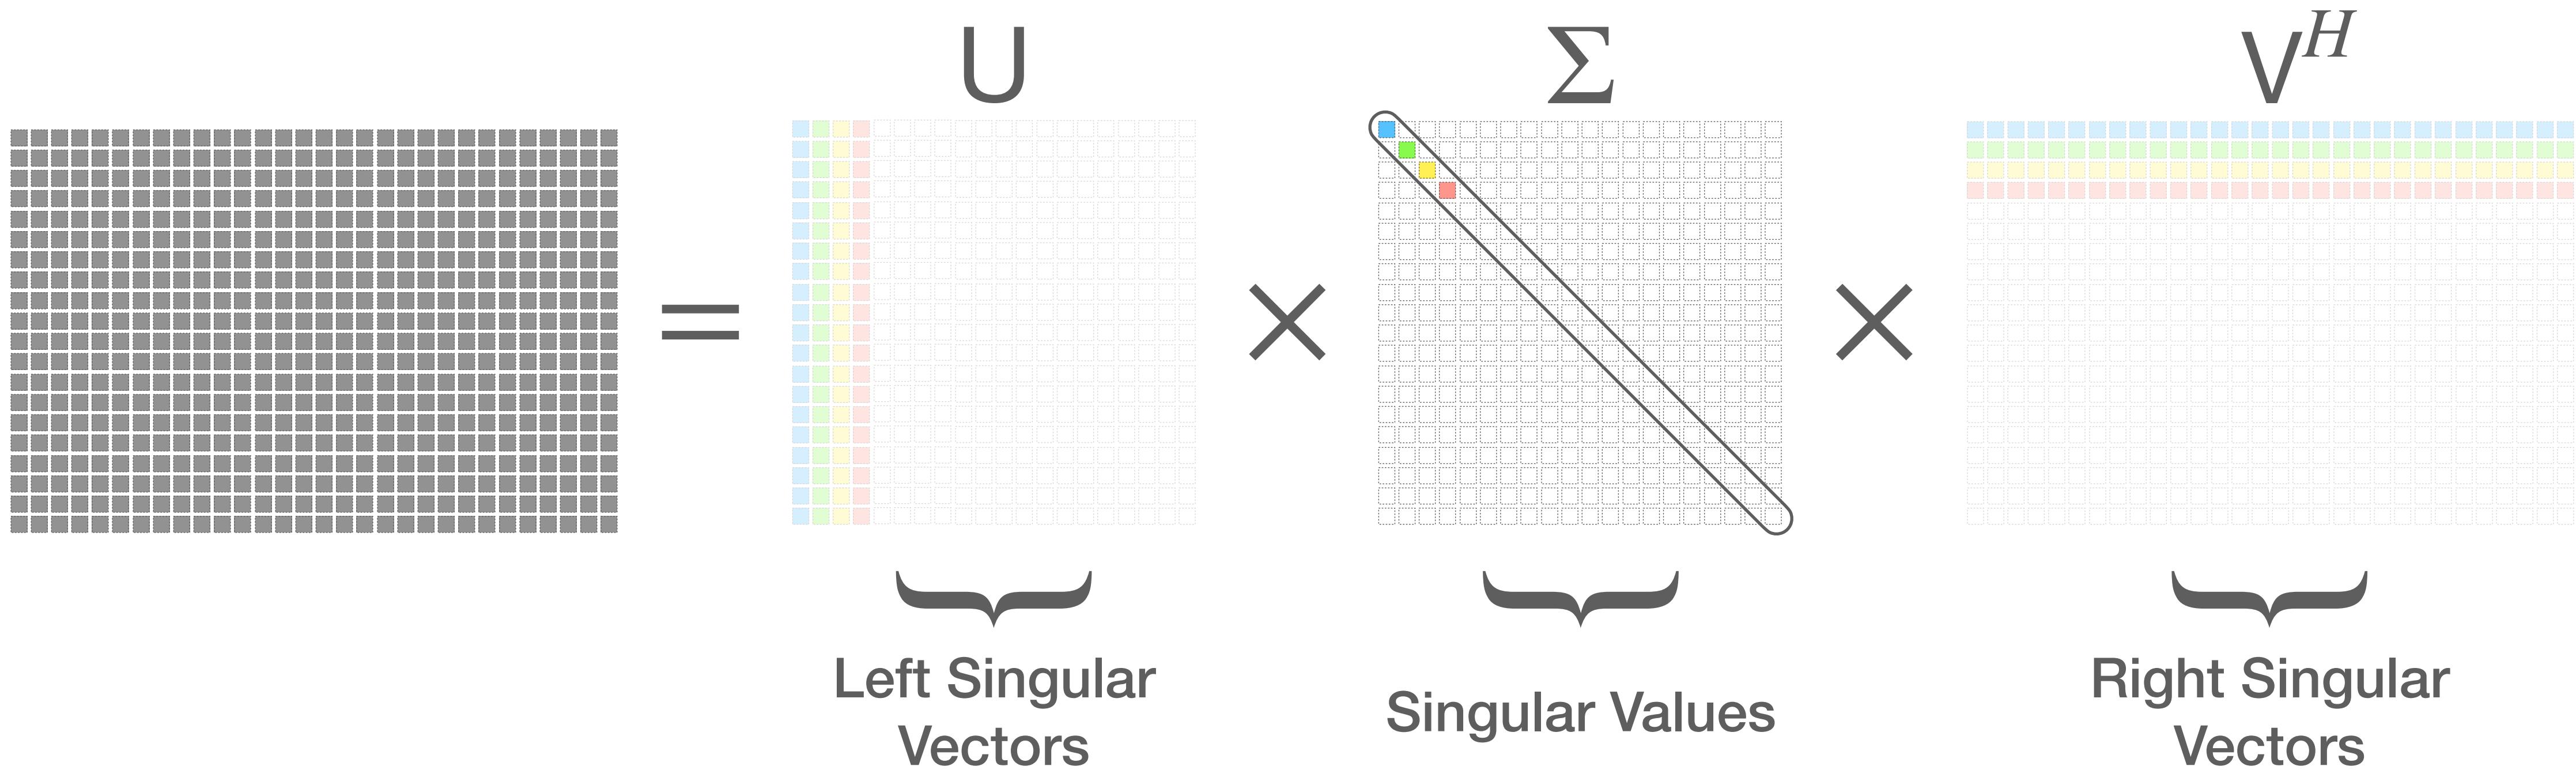

Connection to Sparsity

$$\text{Matrix} = U \times \Sigma \times V^H$$

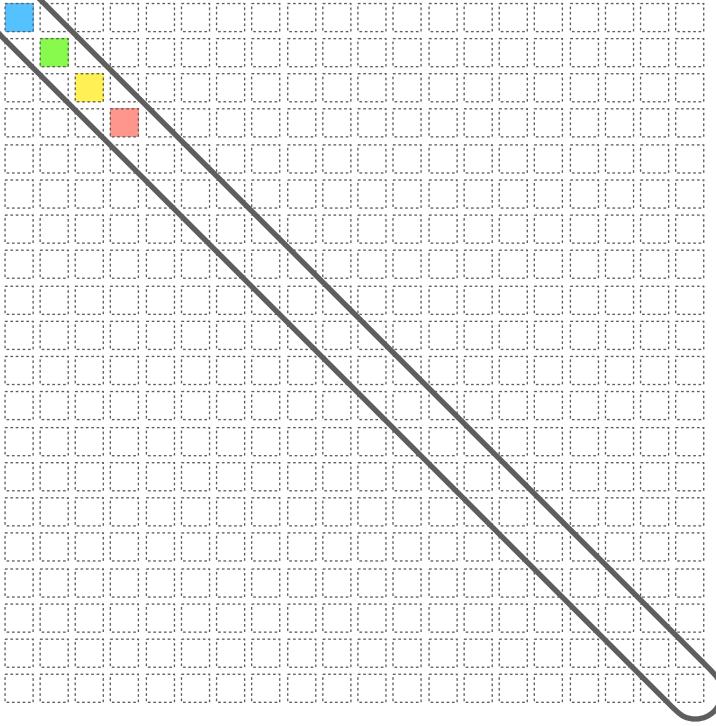

The diagram illustrates the Singular Value Decomposition (SVD) of a matrix. A large gray square matrix is shown on the left, followed by an equals sign. To its right is the product of three matrices: U , Σ , and V^H . The U matrix is composed of several colored vertical columns (blue, green, yellow, red). The Σ matrix is a diagonal matrix with only a few non-zero entries (blue, green, yellow, red). The V^H matrix is also composed of several colored vertical columns (blue, green, yellow, red). Brackets below each matrix indicate their components: the first bracket under U is labeled "Left Singular Vectors", the second bracket under Σ is labeled "Singular Values", and the third bracket under V^H is labeled "Right Singular Vectors".

Connection to Sparsity

Diagonal Vector of Singular Values is Sparse

Connection to Sparsity

$$U^H \times \begin{matrix} \text{A dense matrix} \\ \text{(represented by a grid)} \end{matrix} \times V = \Sigma$$

U^H and V are like sparsifying transforms

But we don't need to know them *a priori*, only that they *exist*

Low-Rank Methods

Basic Premise

- You want to reconstruct your data in the presence of under-sampling, noise, or other corruption/perturbation
- Conventional reconstruction models find the image(s) that best fit the measured k-space, in a least squares sense
- However, this may not produce the “best” reconstruction in terms of metrics such as MSE, or the problem might be under-determined
- If your data can be represented as a low-rank matrix, you can use that prior knowledge to additionally constrain/regularize the image reconstruction

Recipe

Low-Rank Methods

1. Identify the low-rank matrix data

- e.g., space by time

2. Construct your forward measurement model

- i.e., information about sampling, coil sensitivities, etc.

3. Choose a suitable cost function with low-rank constraint

- e.g., convex or non-convex, local or global low-rank constraints

4. Solve the cost function using an appropriate algorithm

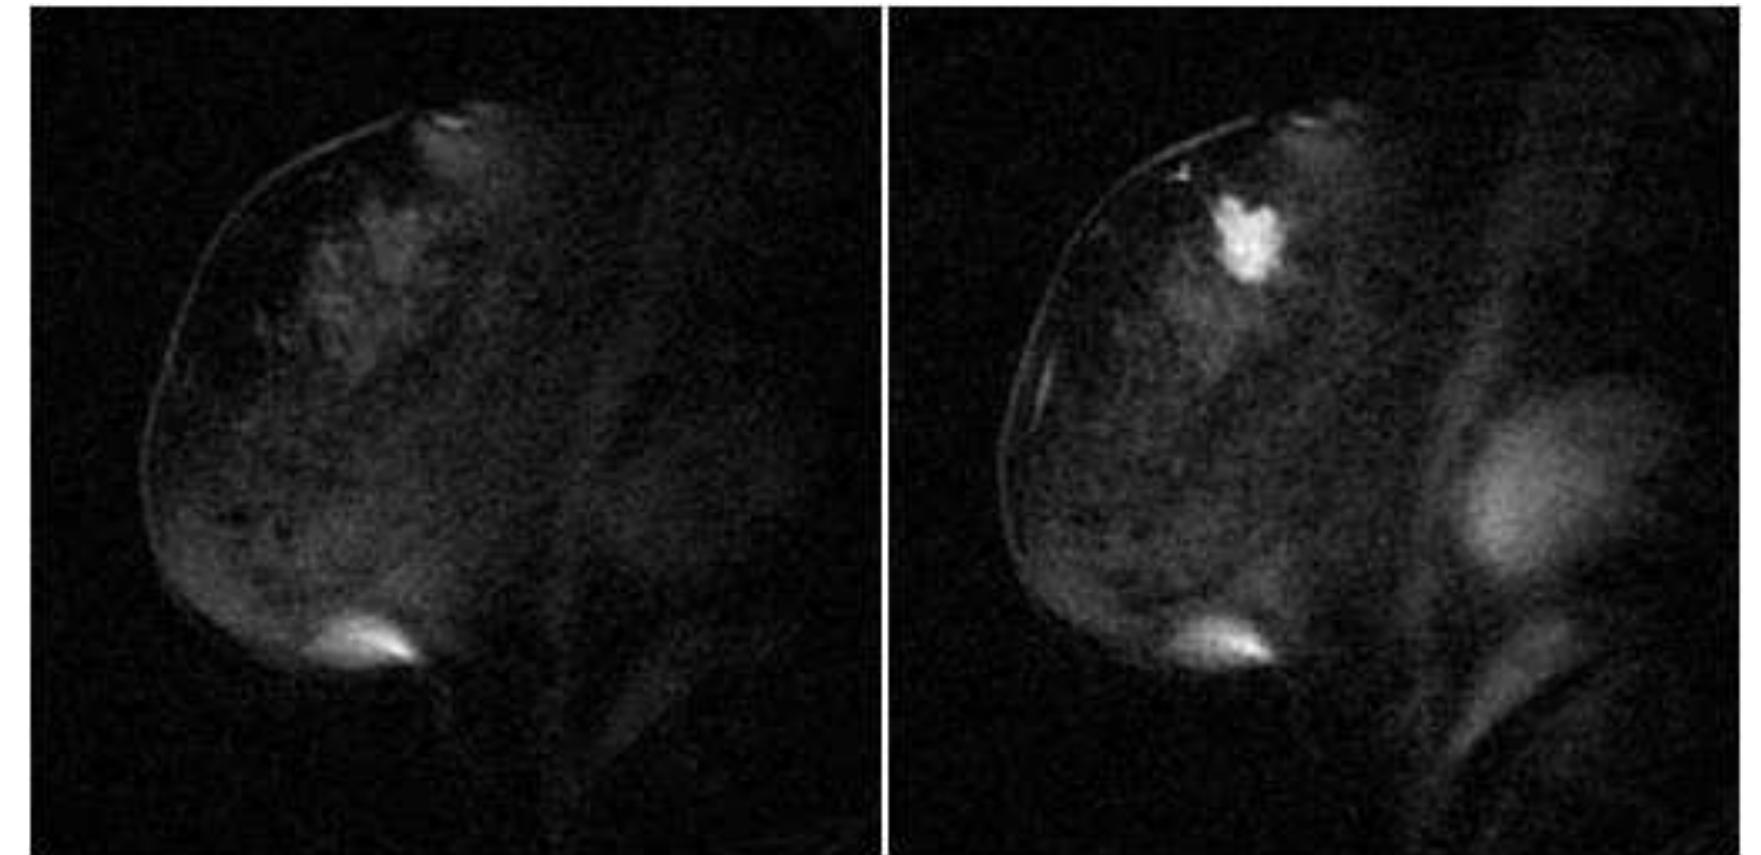

- typically a first order, iterative algorithm

1. Identify appropriate matrix data

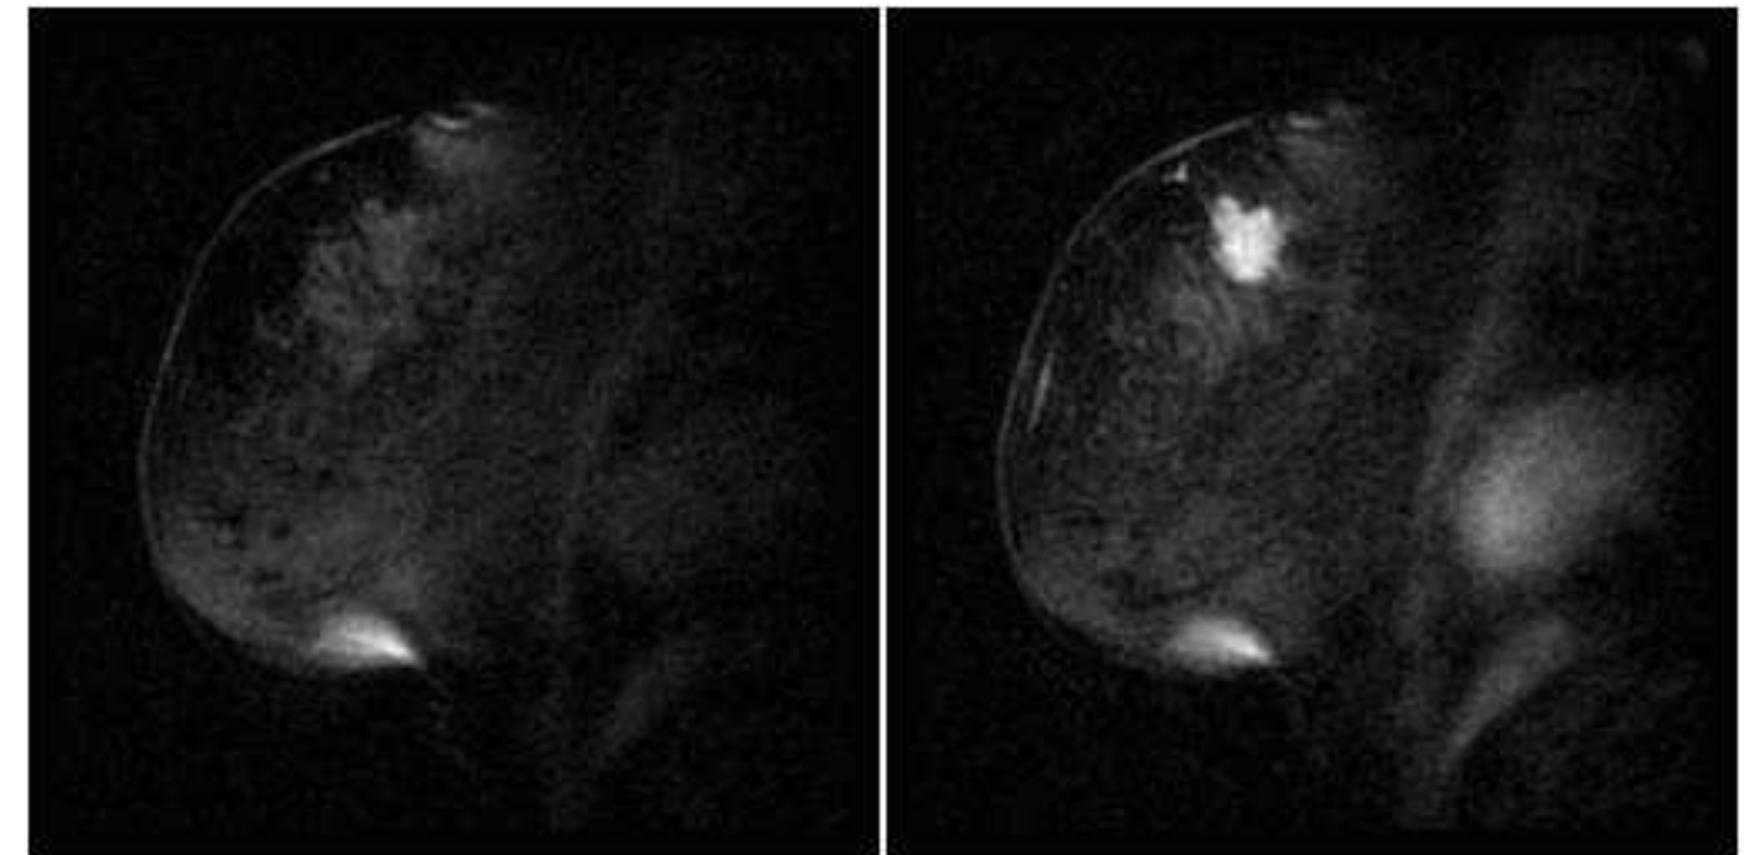

e.g. (Space × Time)

- Space-time matrices are probably the most intuitive
- Signal time-courses are correlated across space
- Many voxels exhibit the same contrast dynamics

Ground Truth

Low-Rank

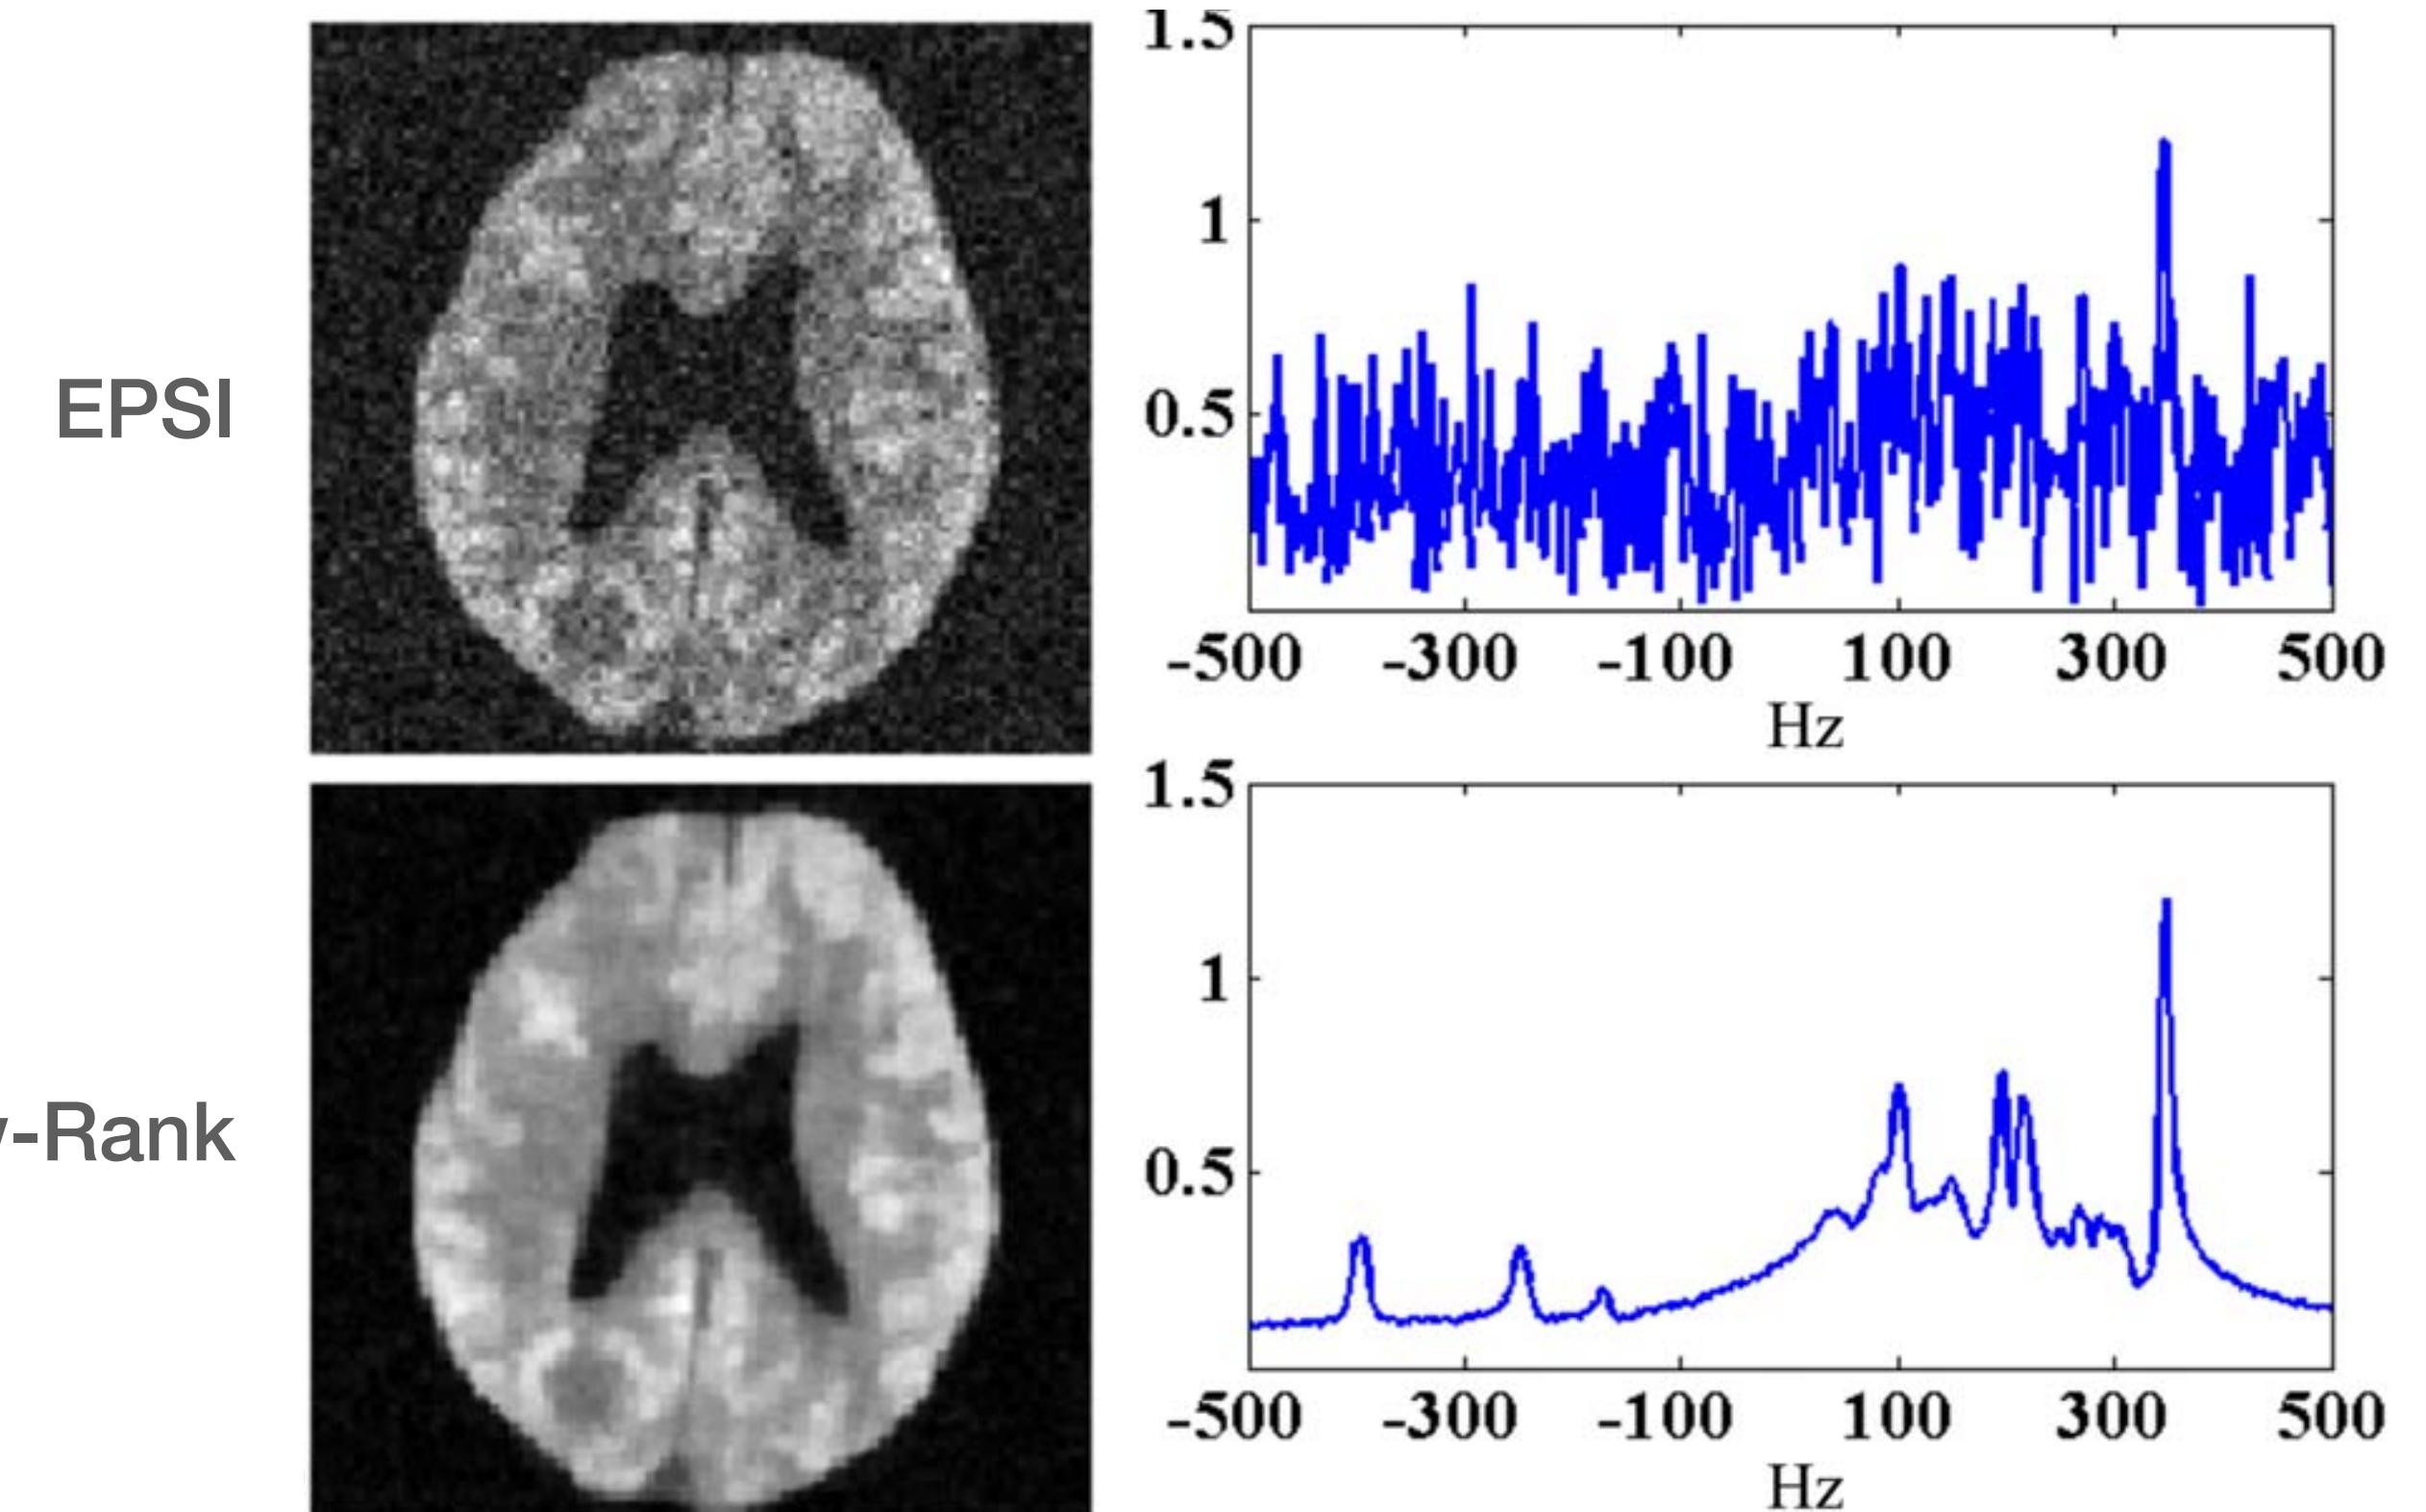

Dynamic Contrast Enhanced Breast

1. Identify appropriate matrix data

e.g. (Space × Spectra)

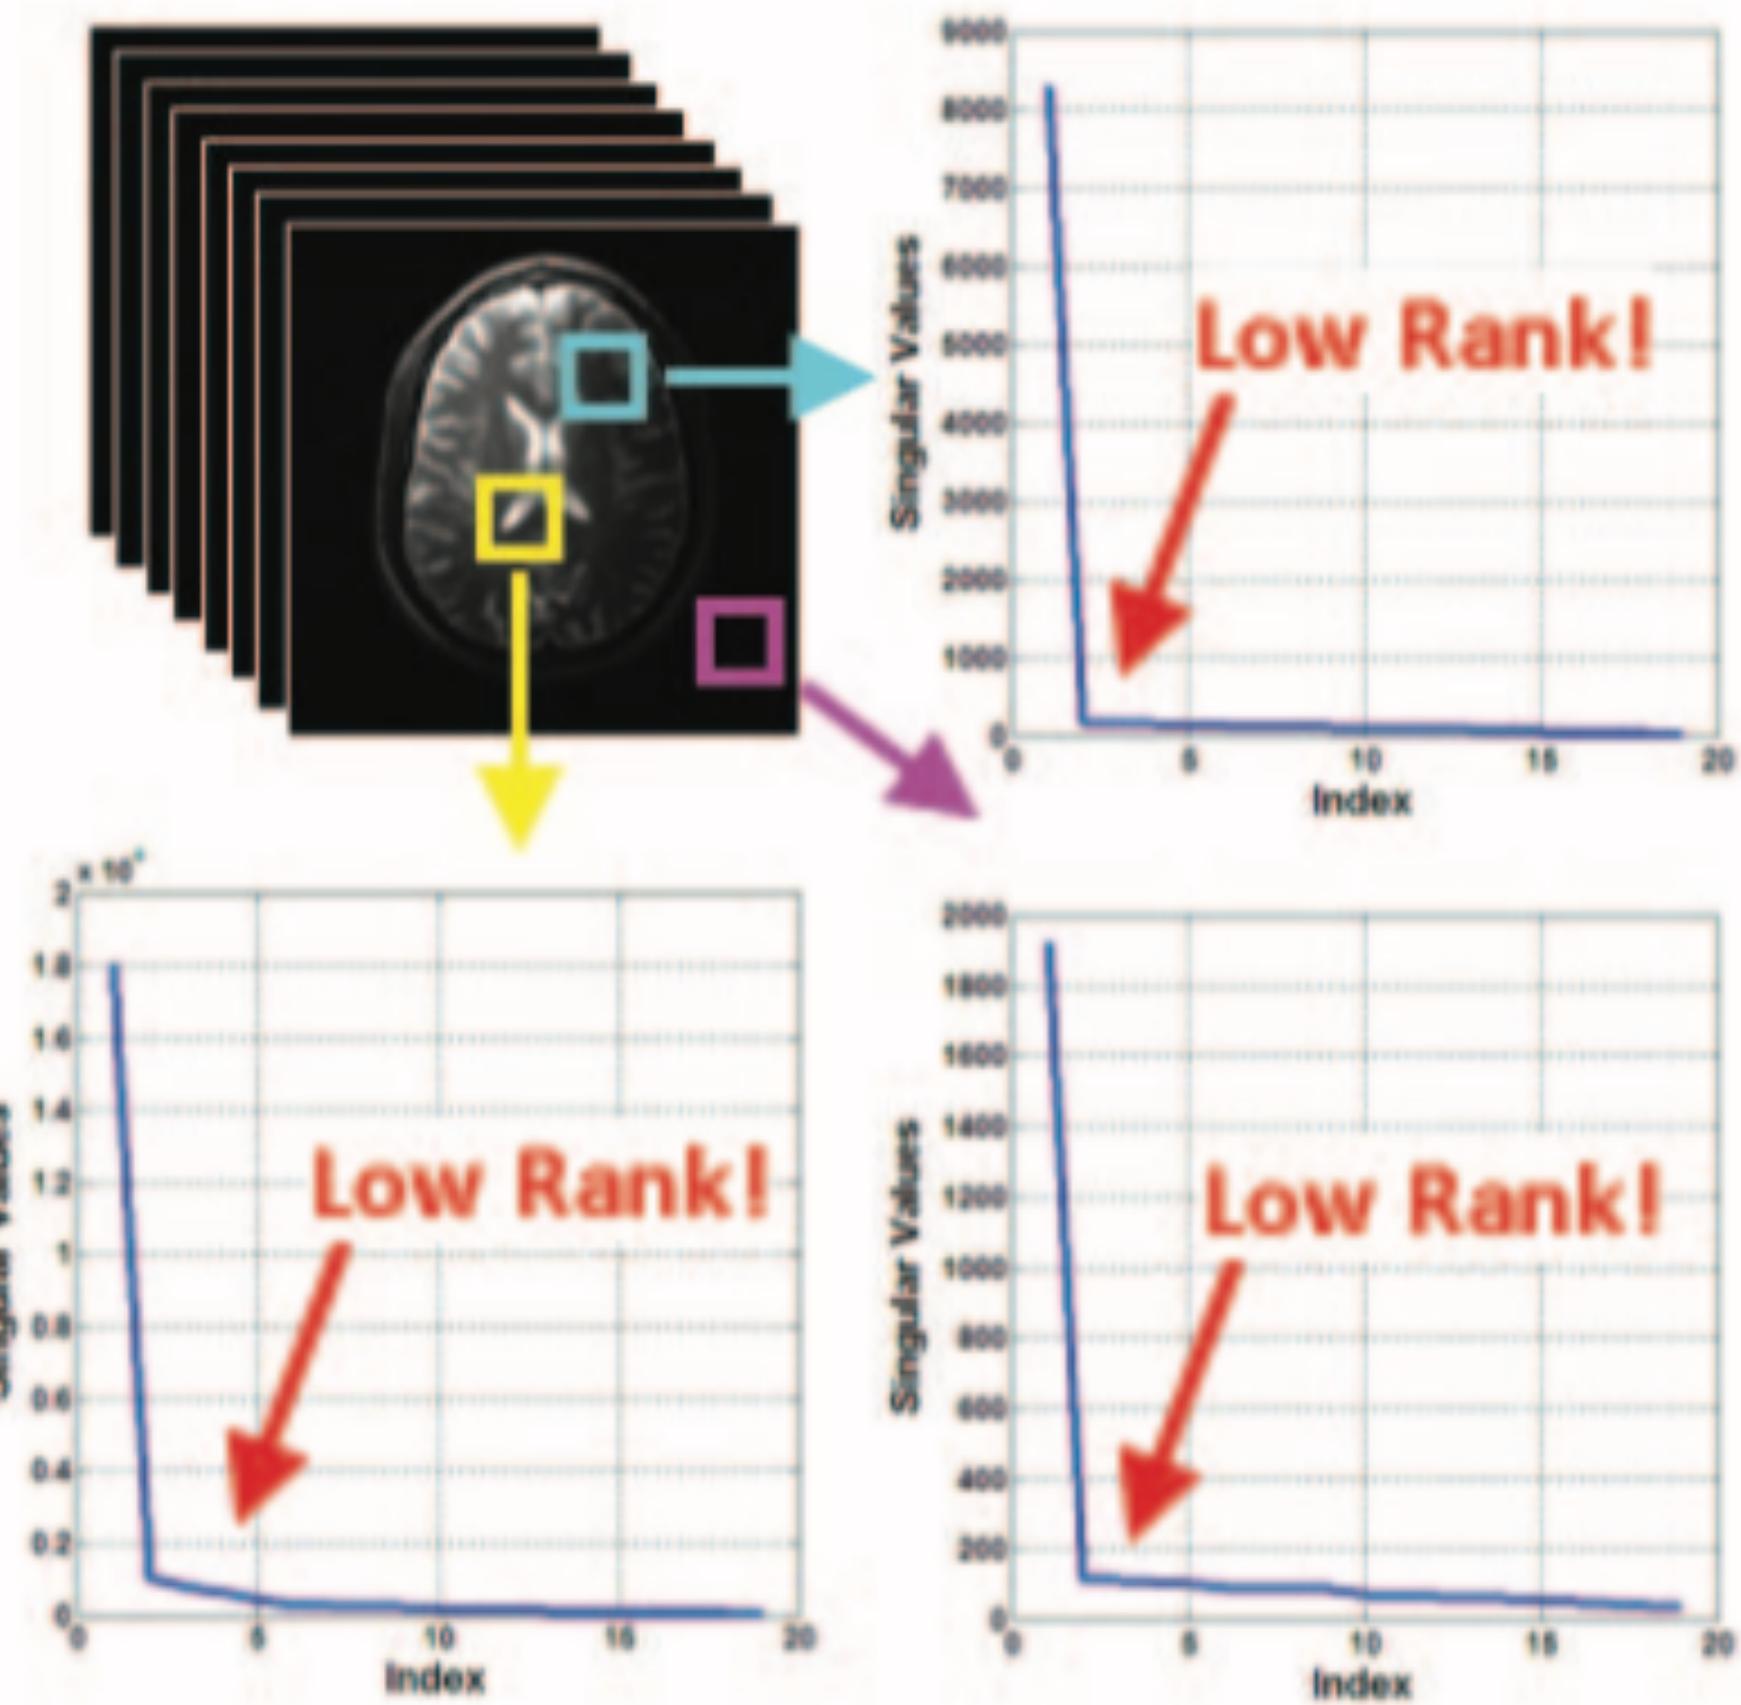

- Spectral content is similar across voxels

1. Identify appropriate matrix data

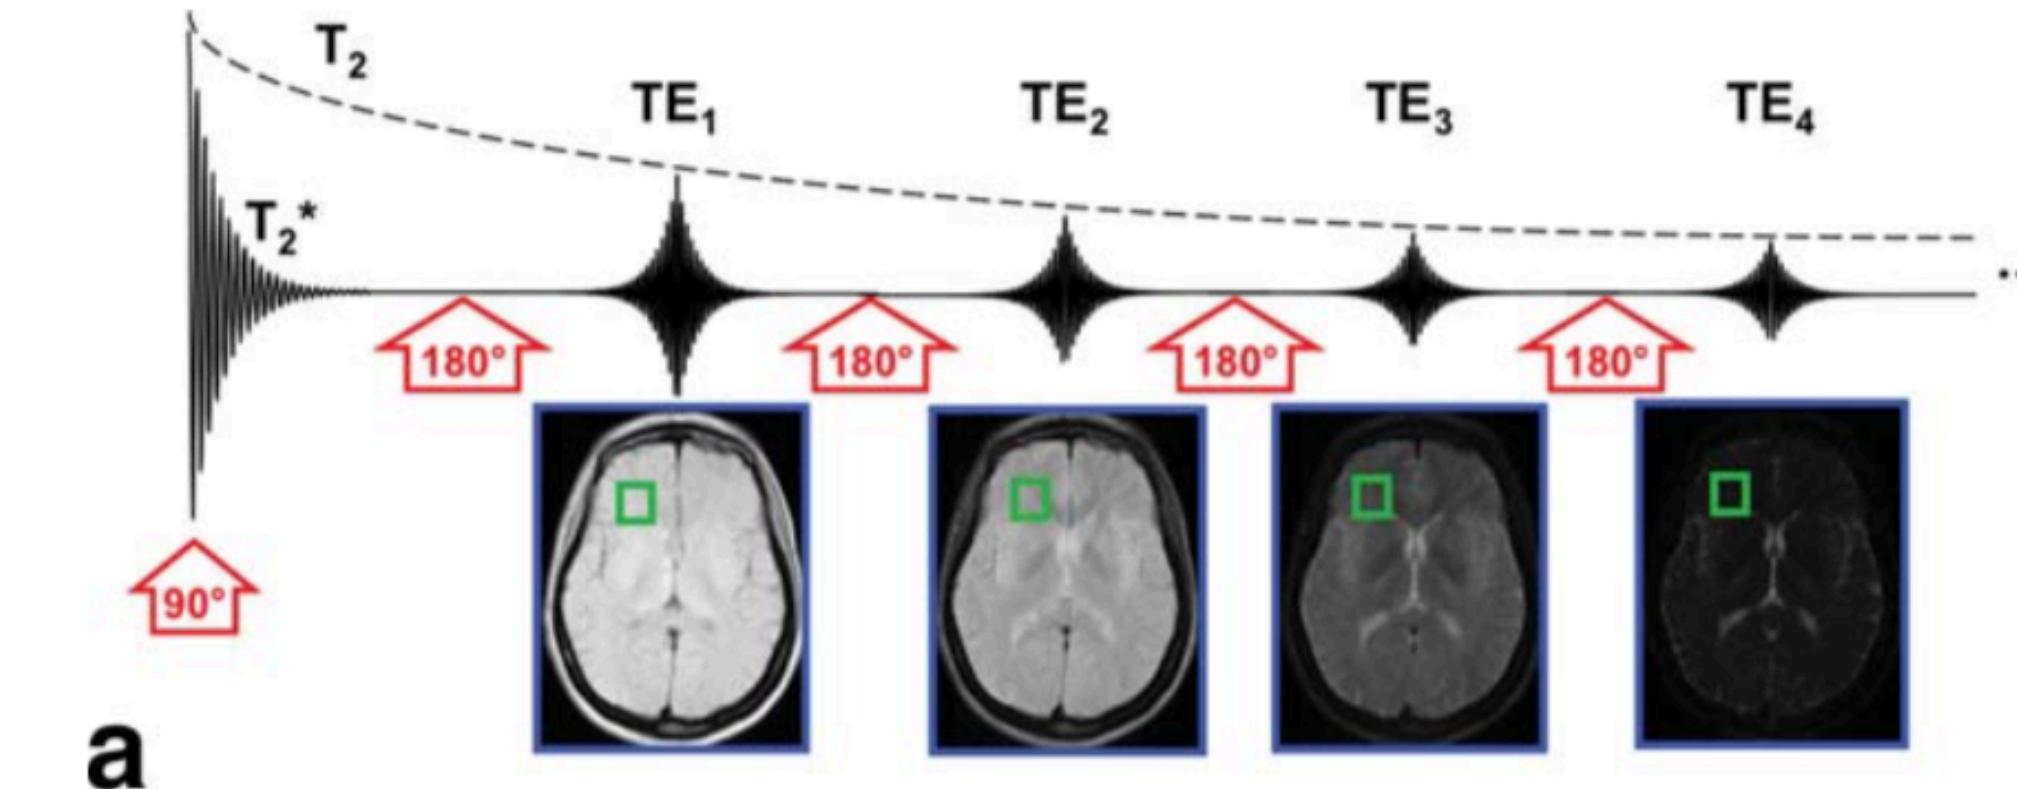

e.g. (Space × Coils)

- Local spatial information is shared across coils

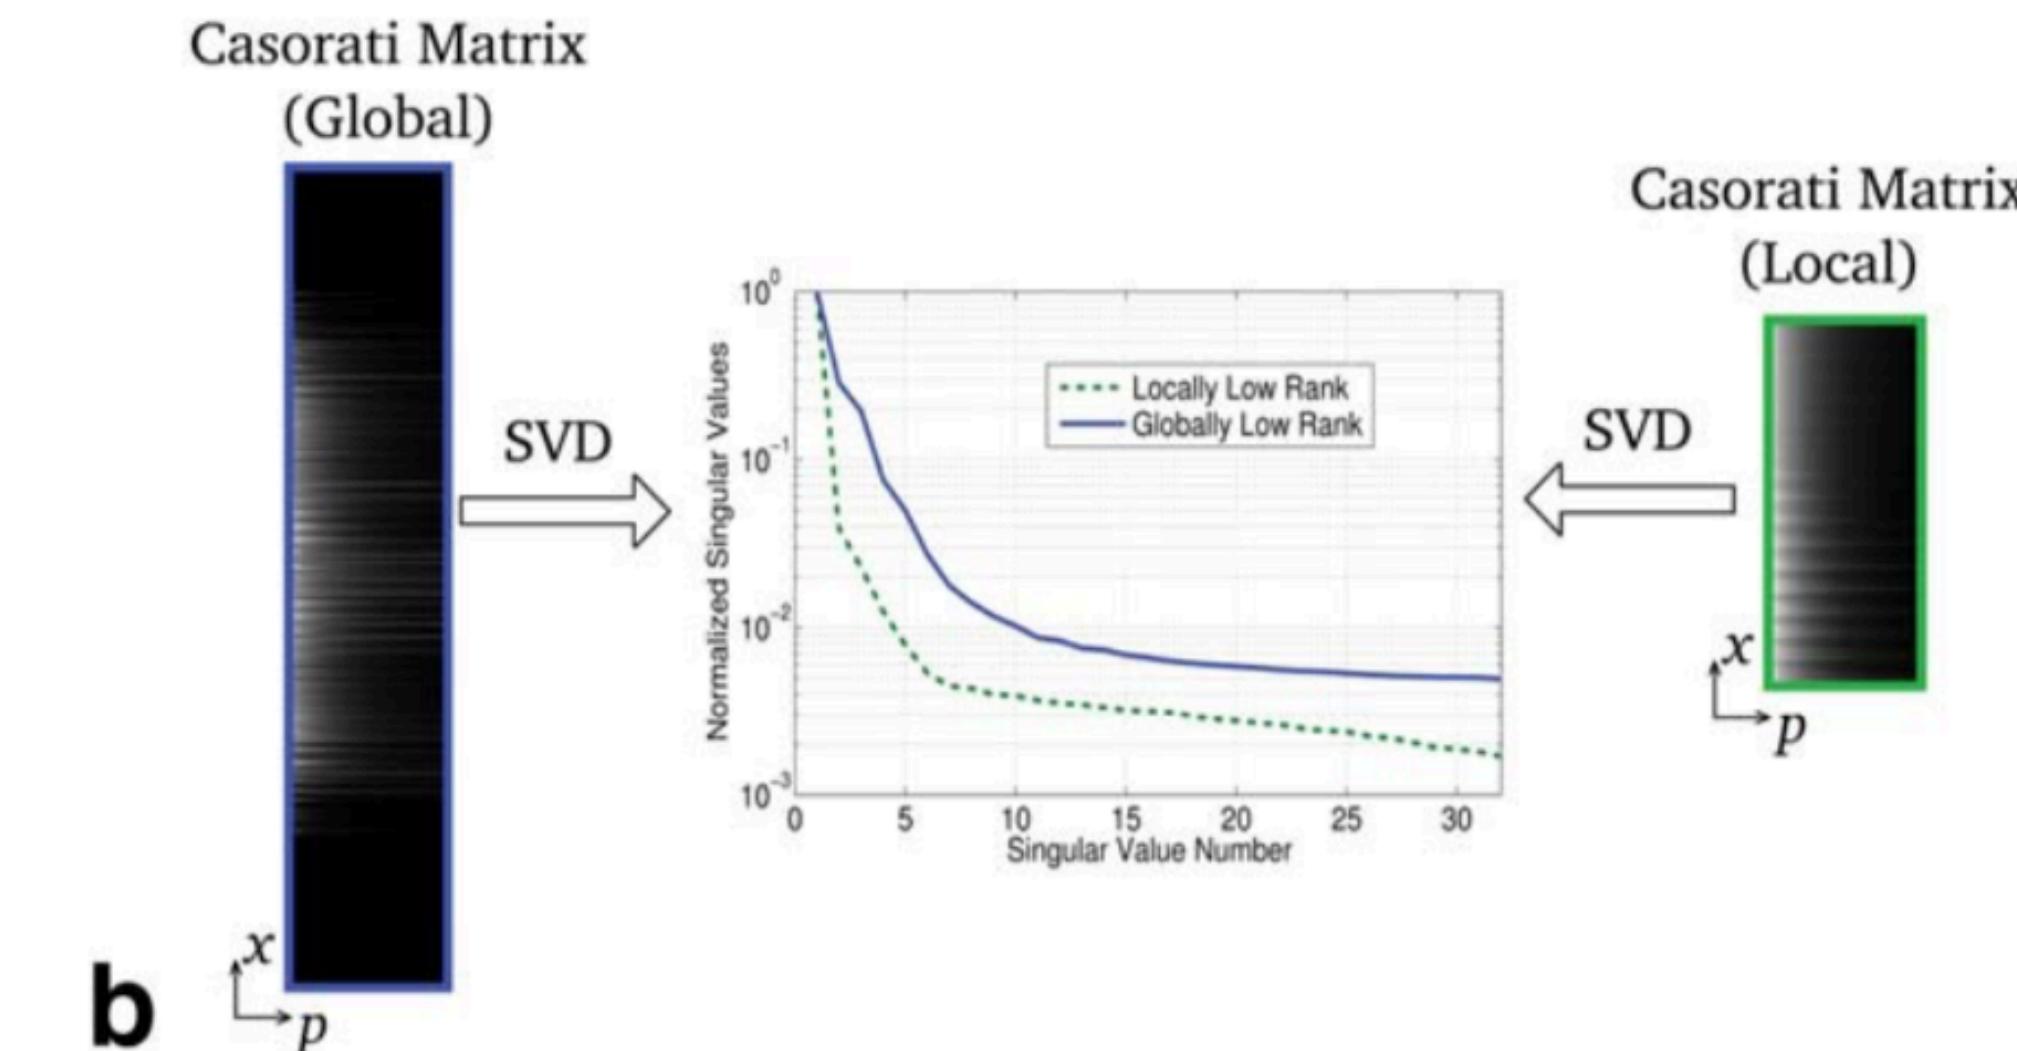

1. Identify appropriate matrix data

e.g. (Space \times TE)

a

- Voxels or spatial features are correlated across echo time

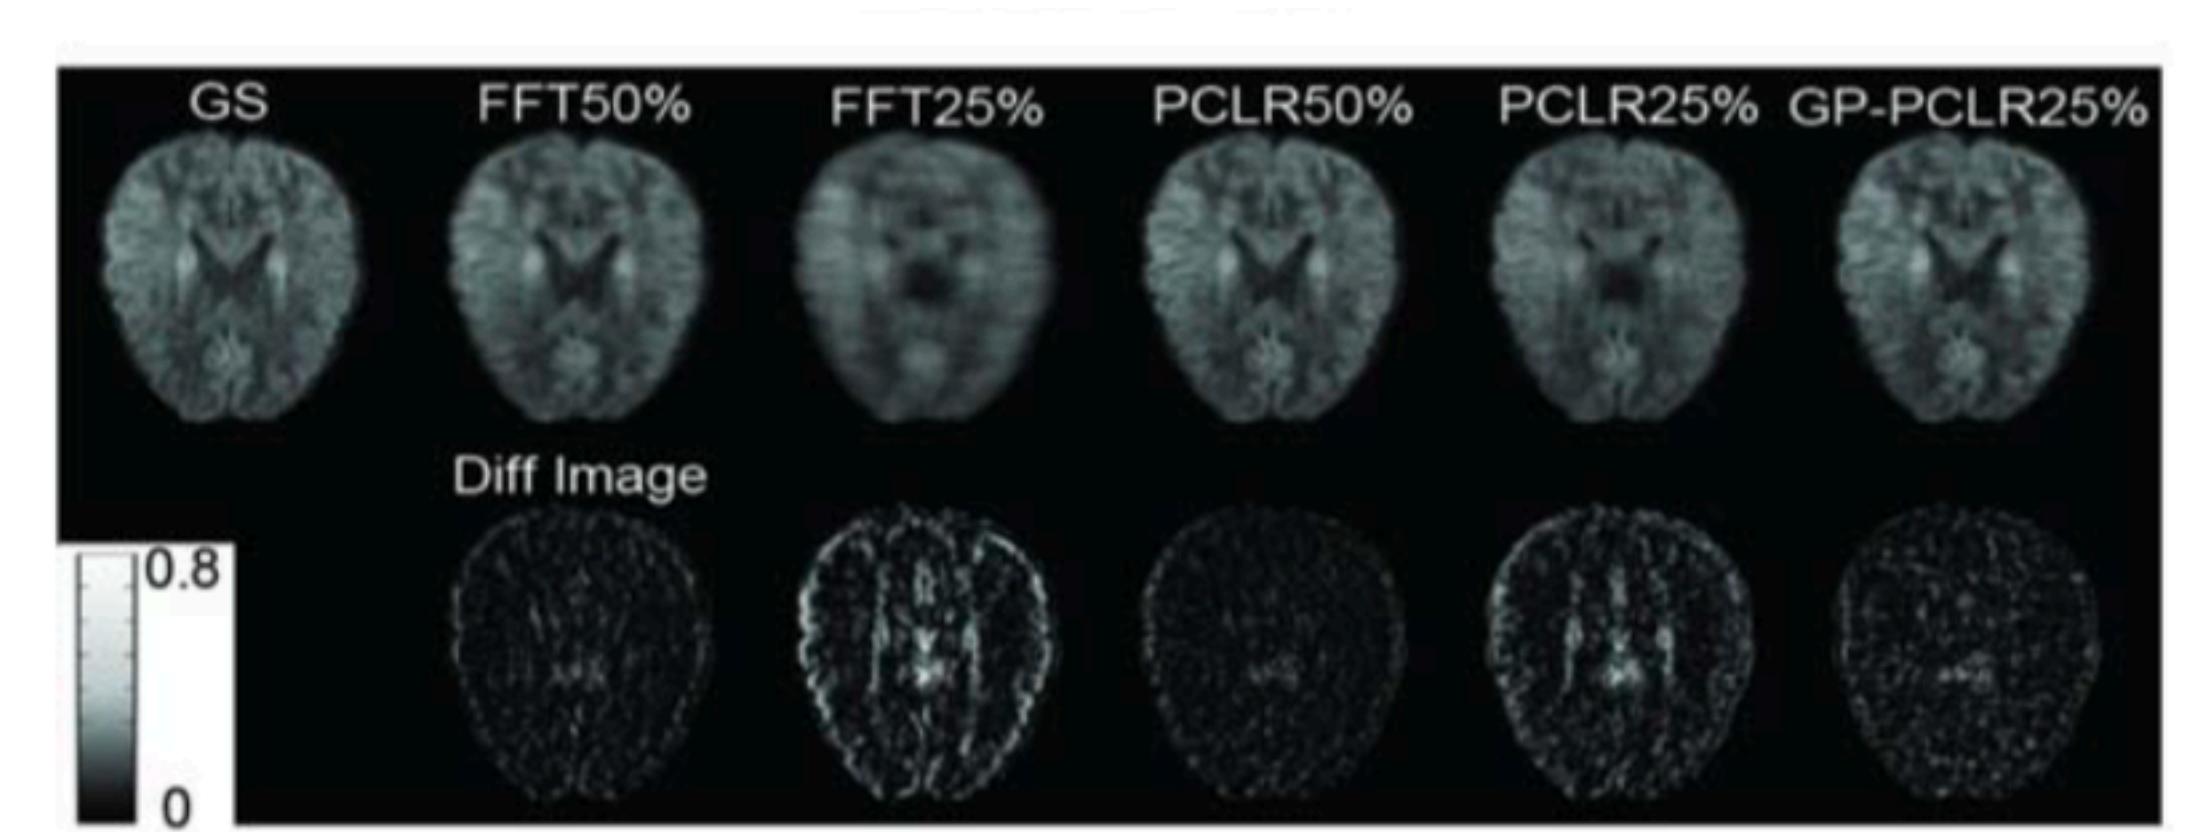

b

1. Identify appropriate matrix data

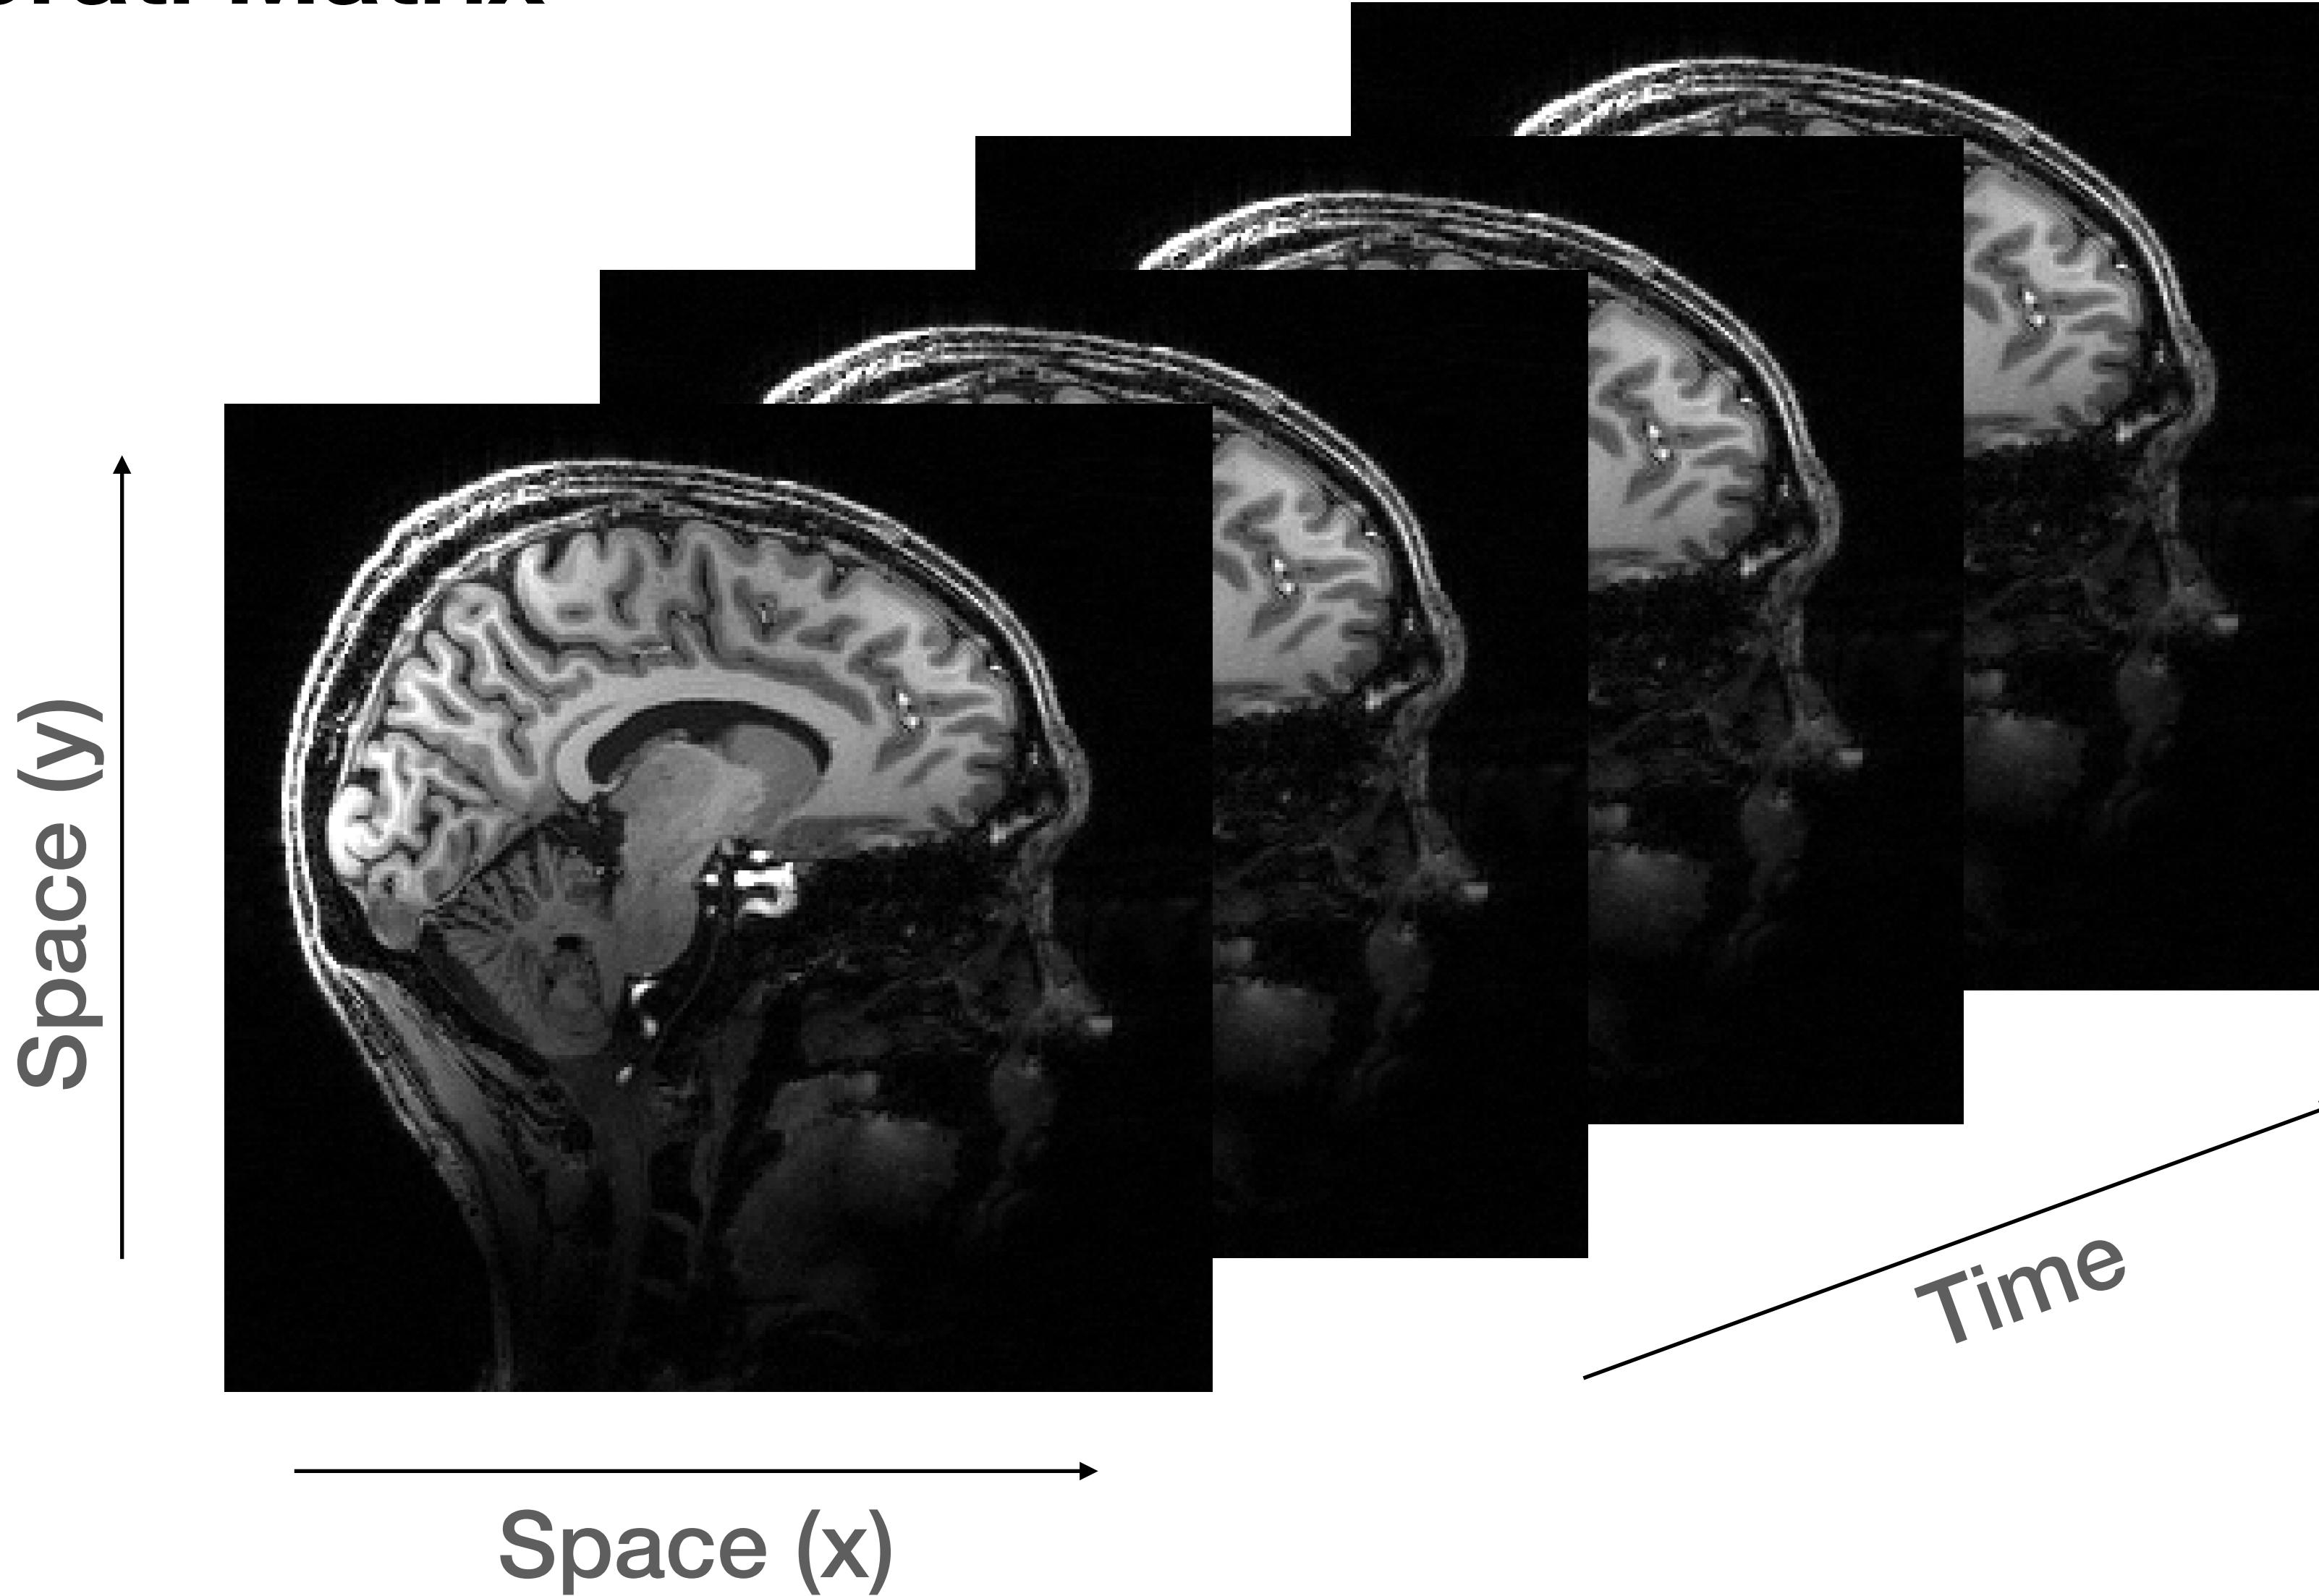

e.g. (Space × Diffusion Encoding)

- Voxel contrasts are correlated across diffusion encodings

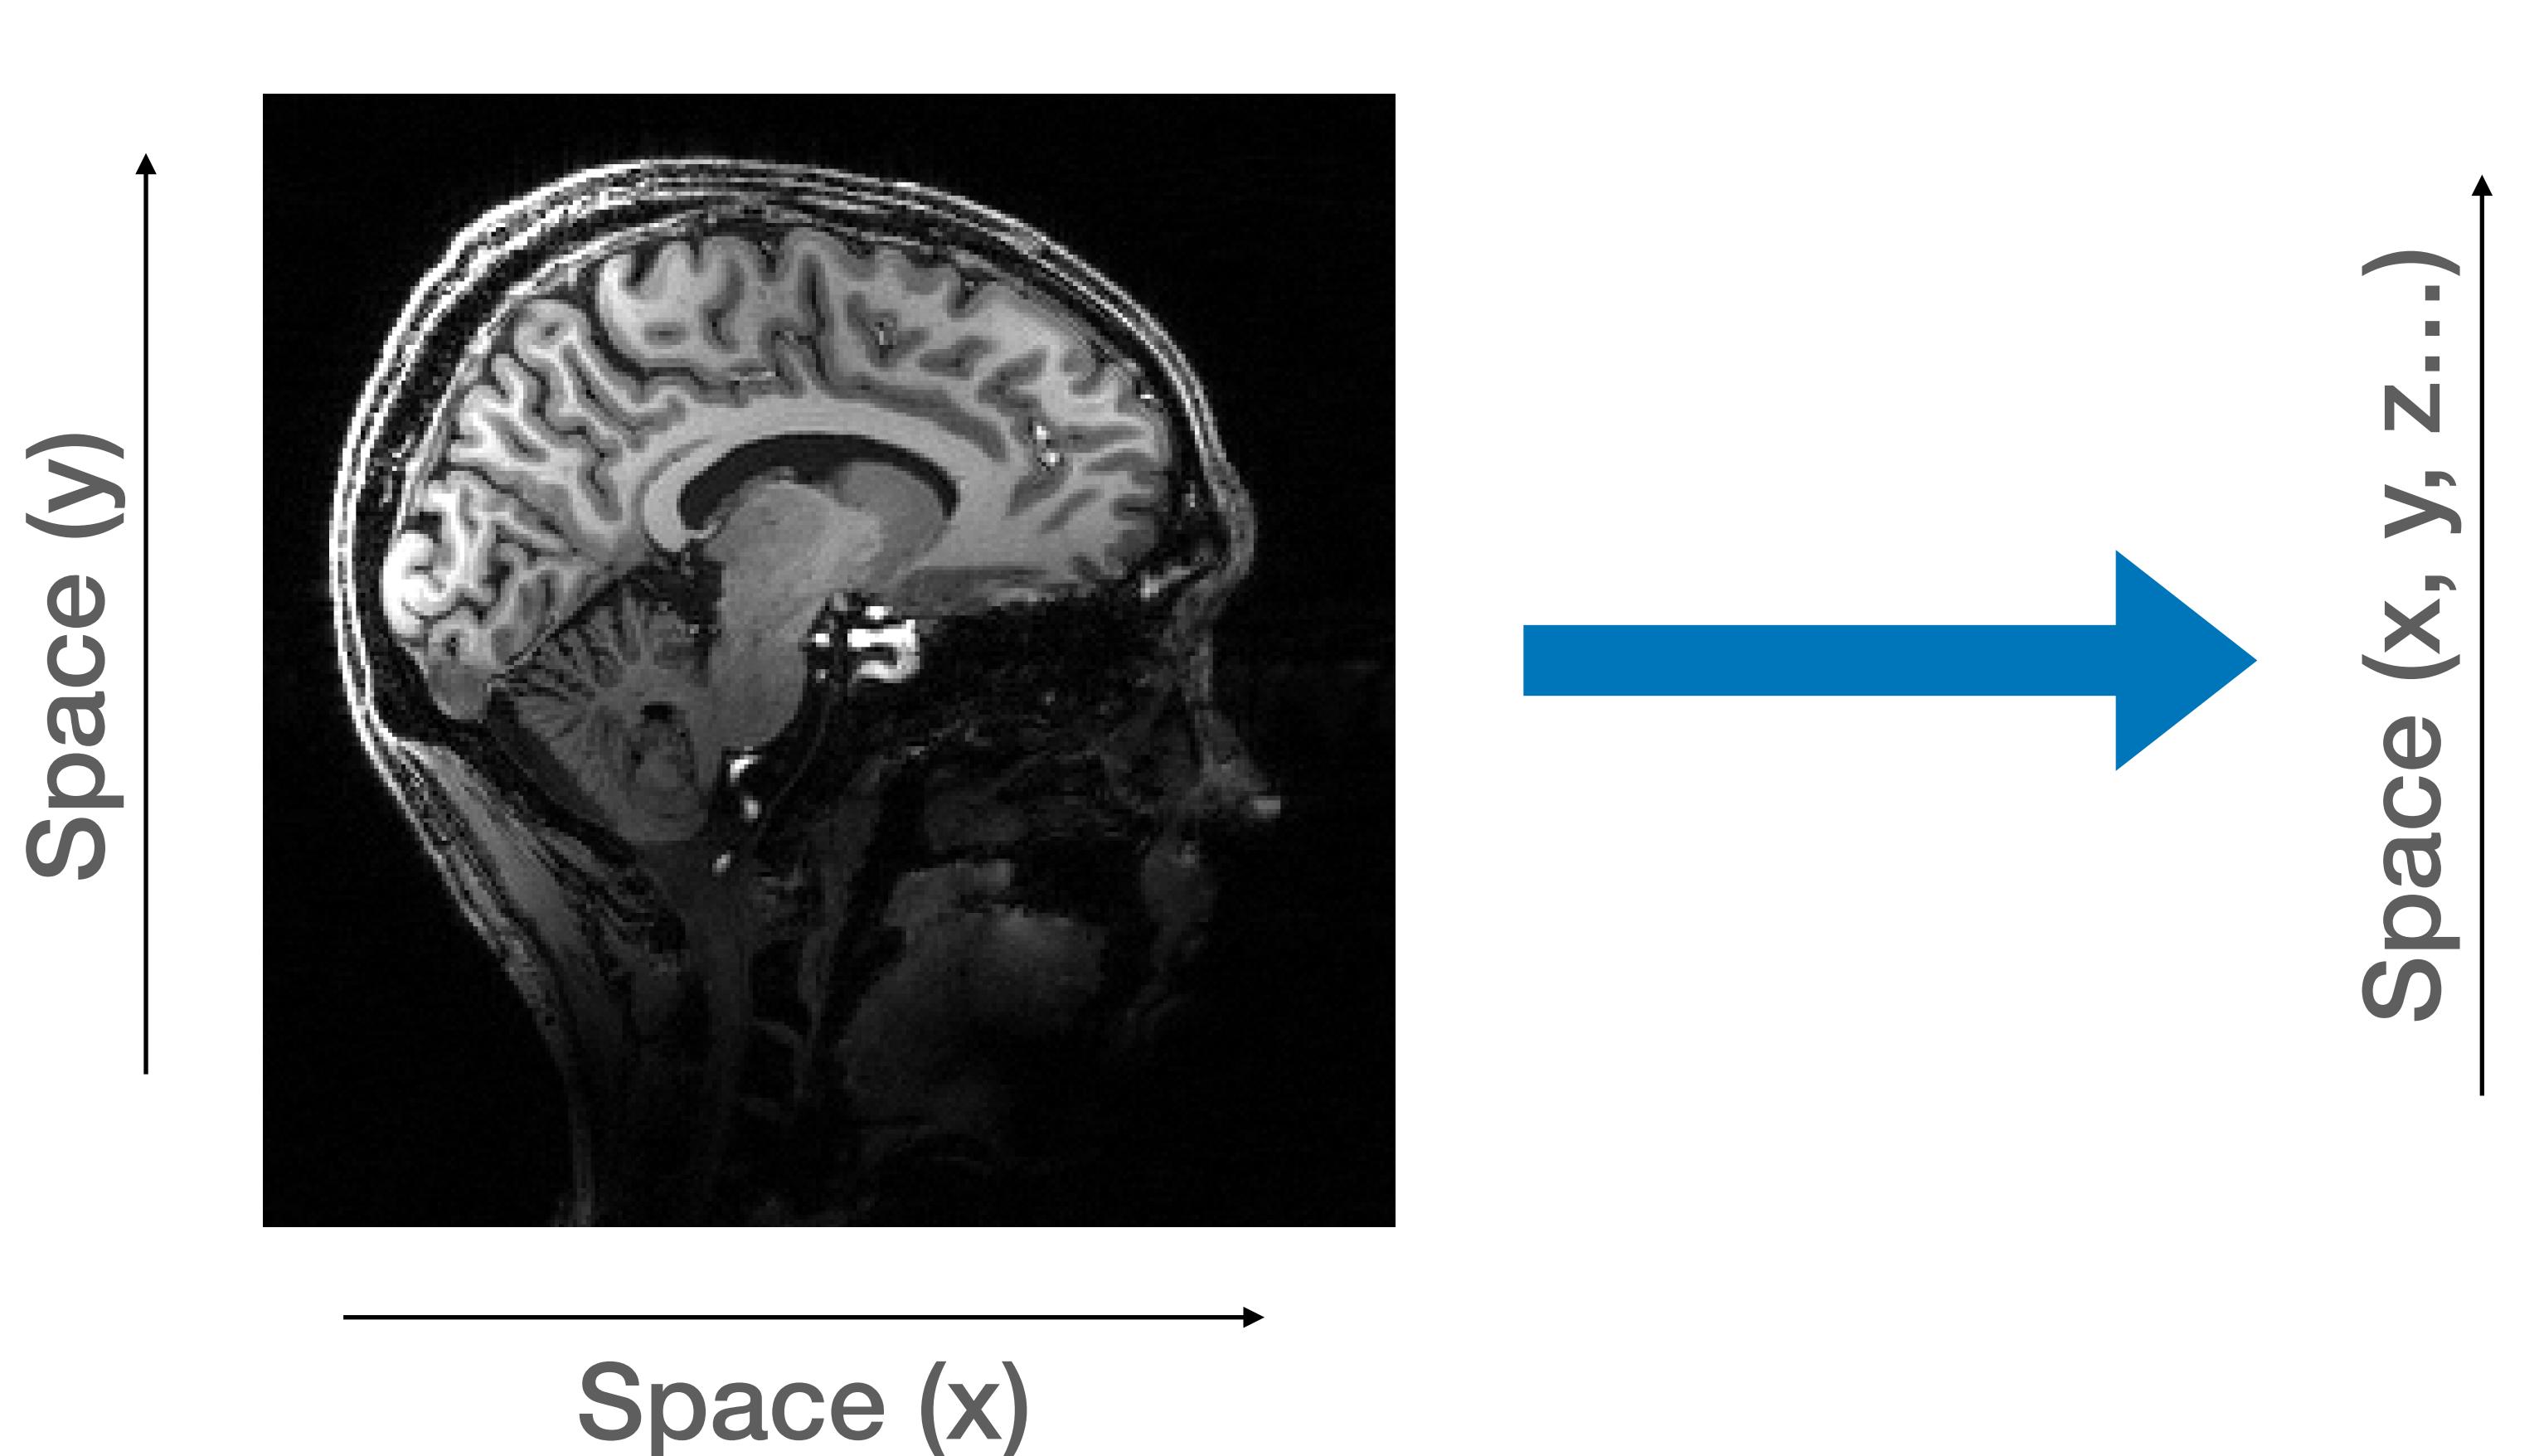

1. Identify appropriate matrix data

n.b. “Casorati Matrix”

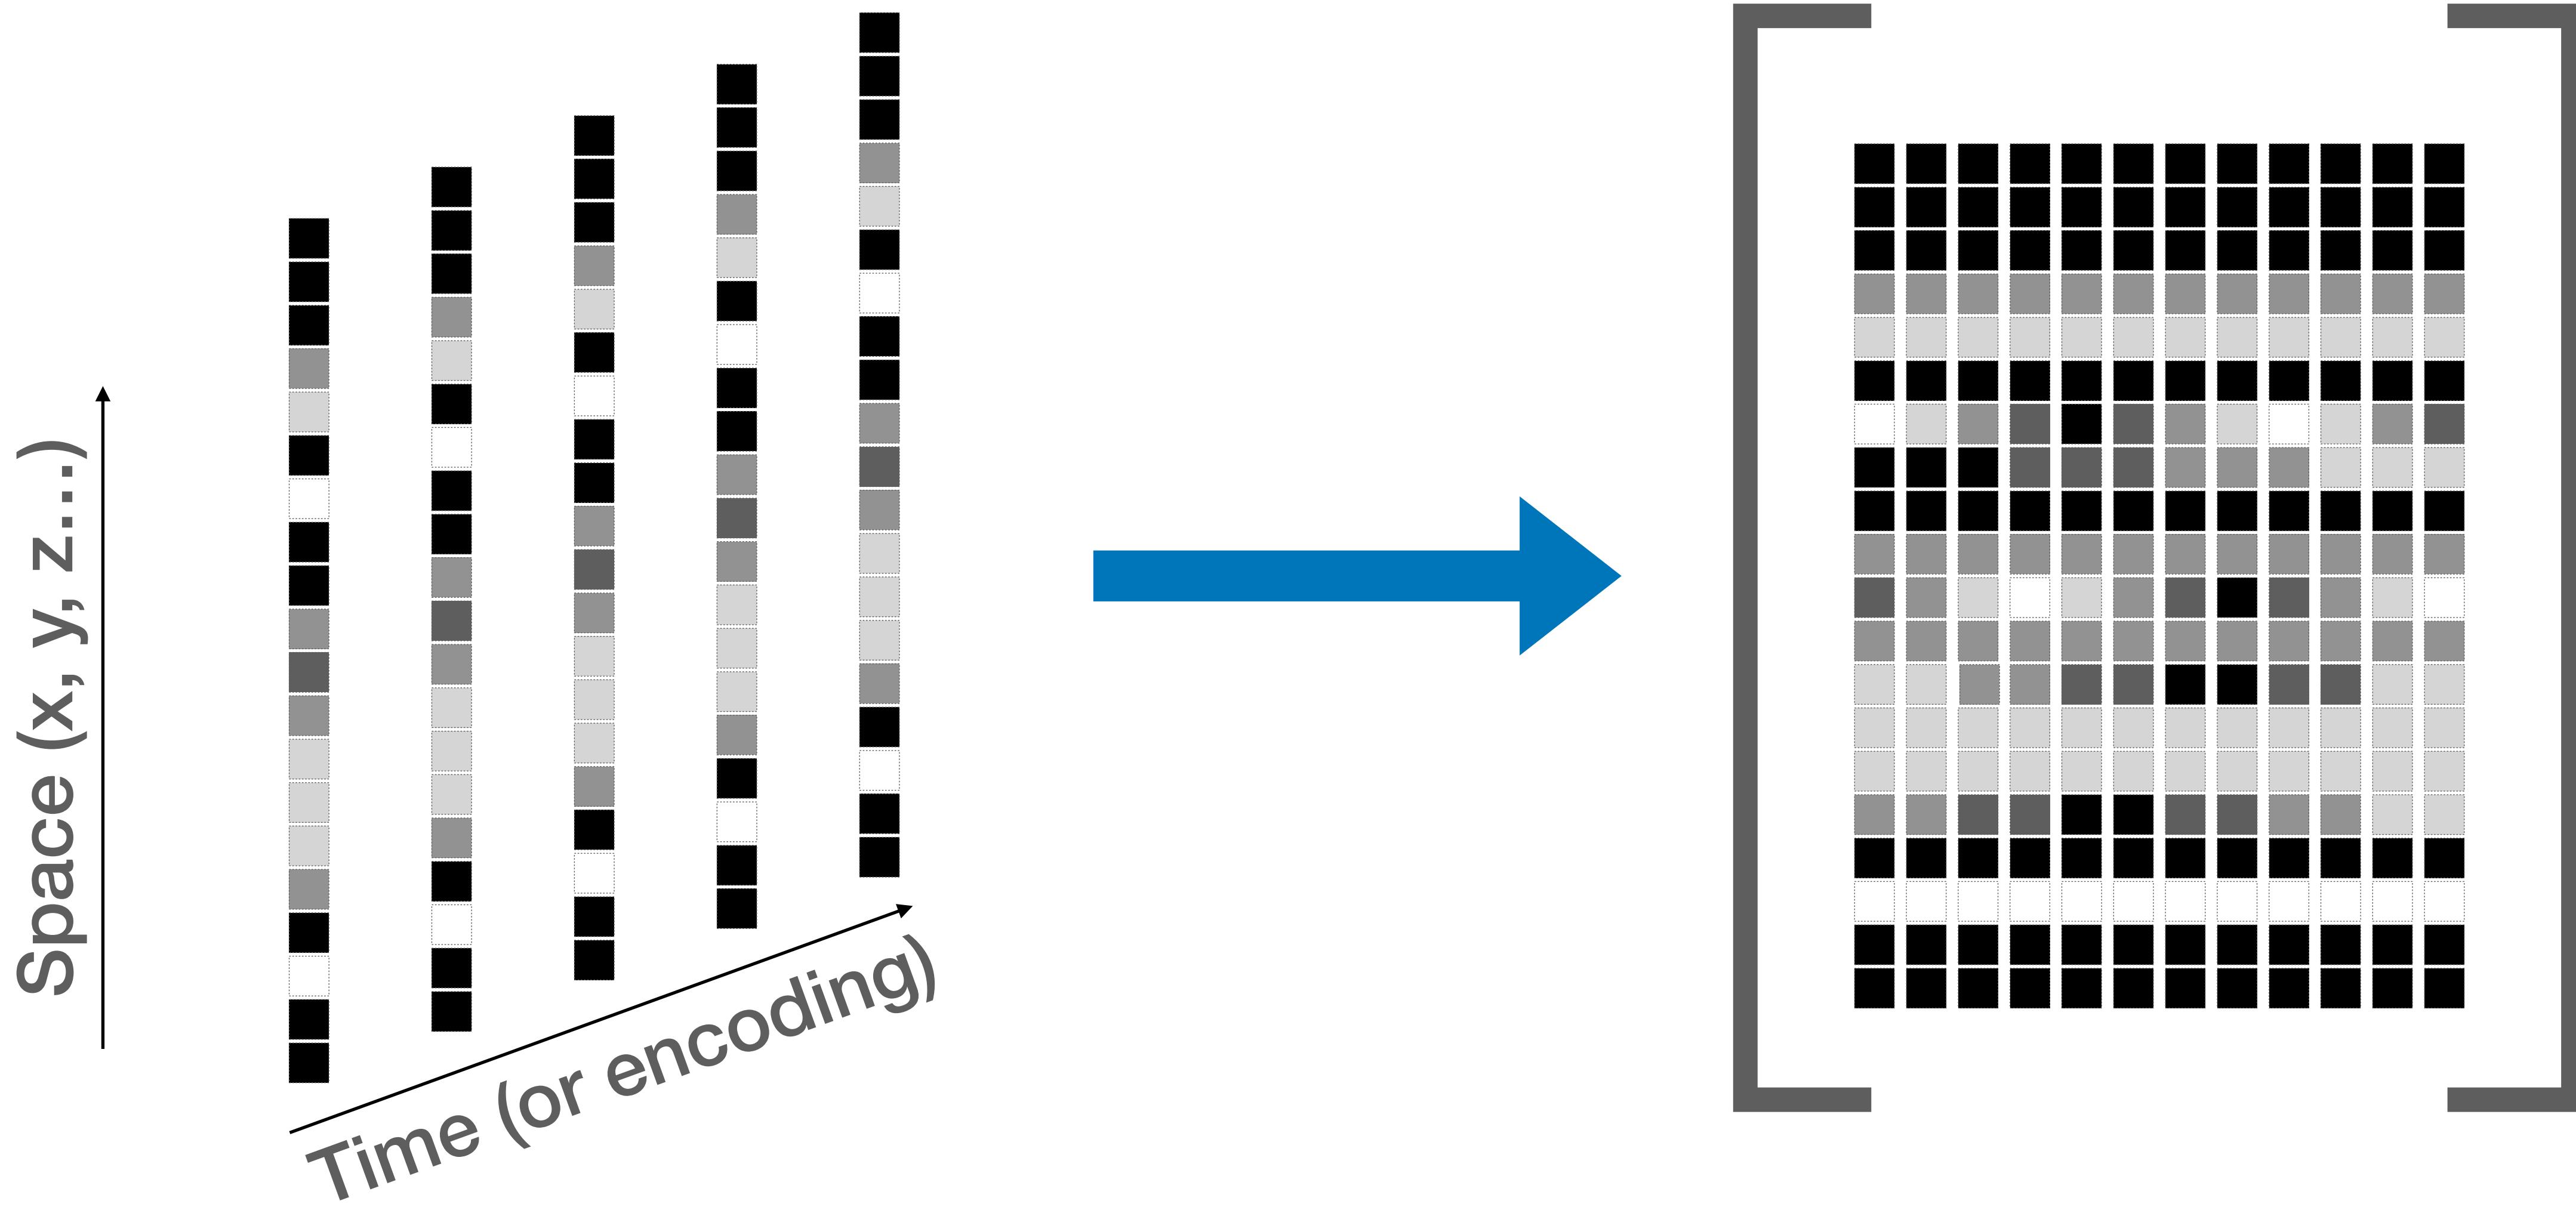

1. Identify appropriate matrix data

n.b. “Casorati Matrix”

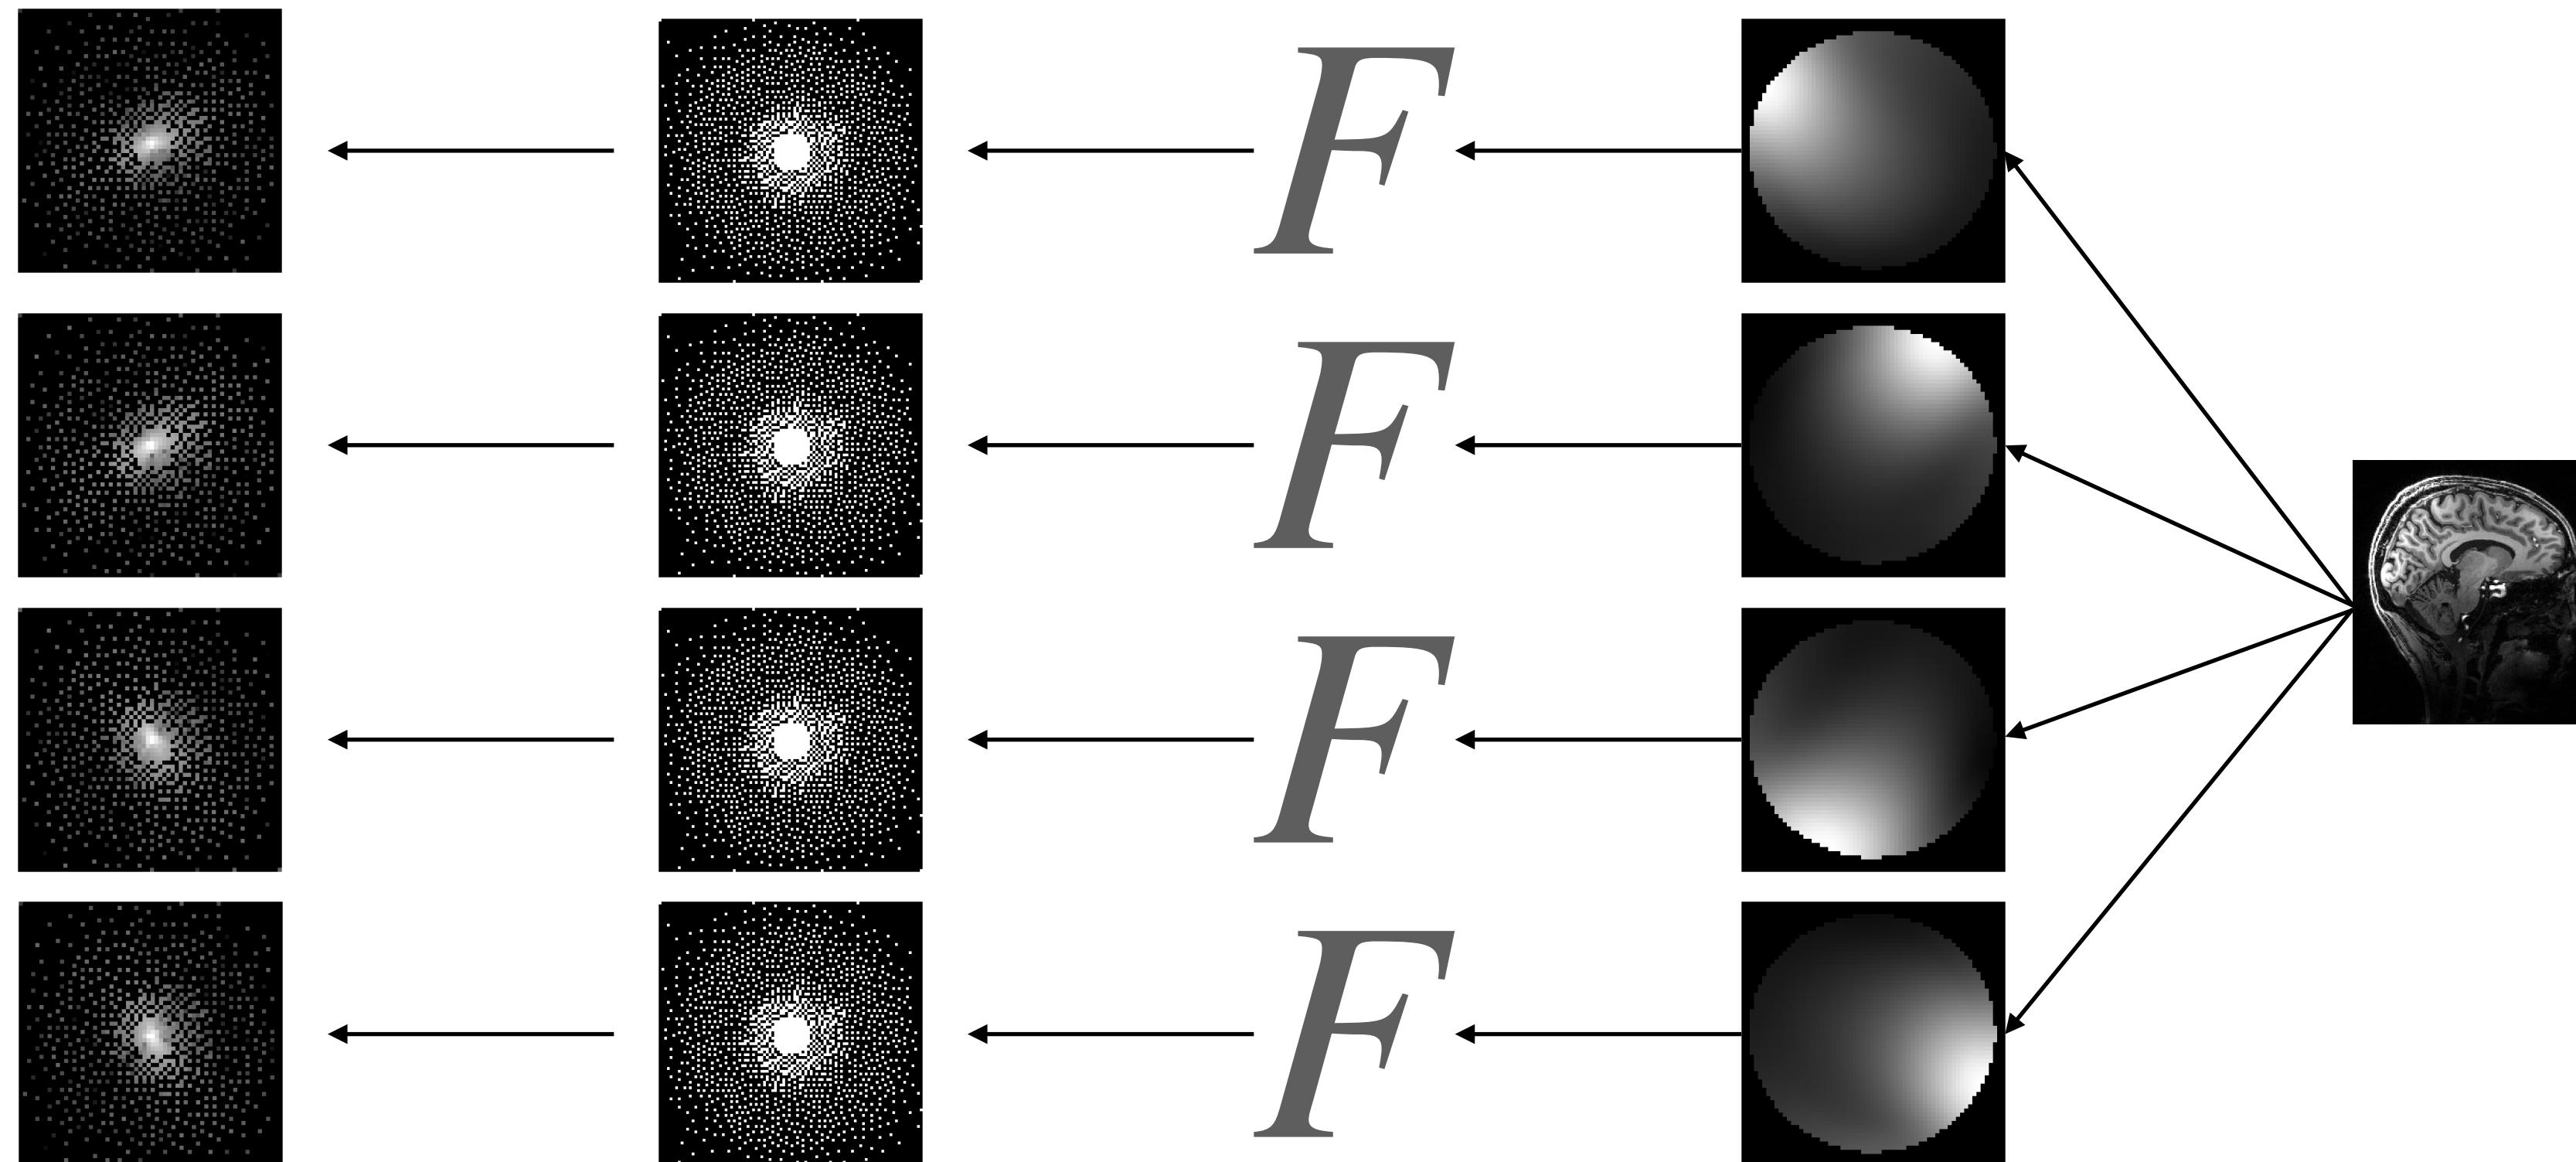

1. Identify appropriate matrix data

n.b. “Casorati Matrix”

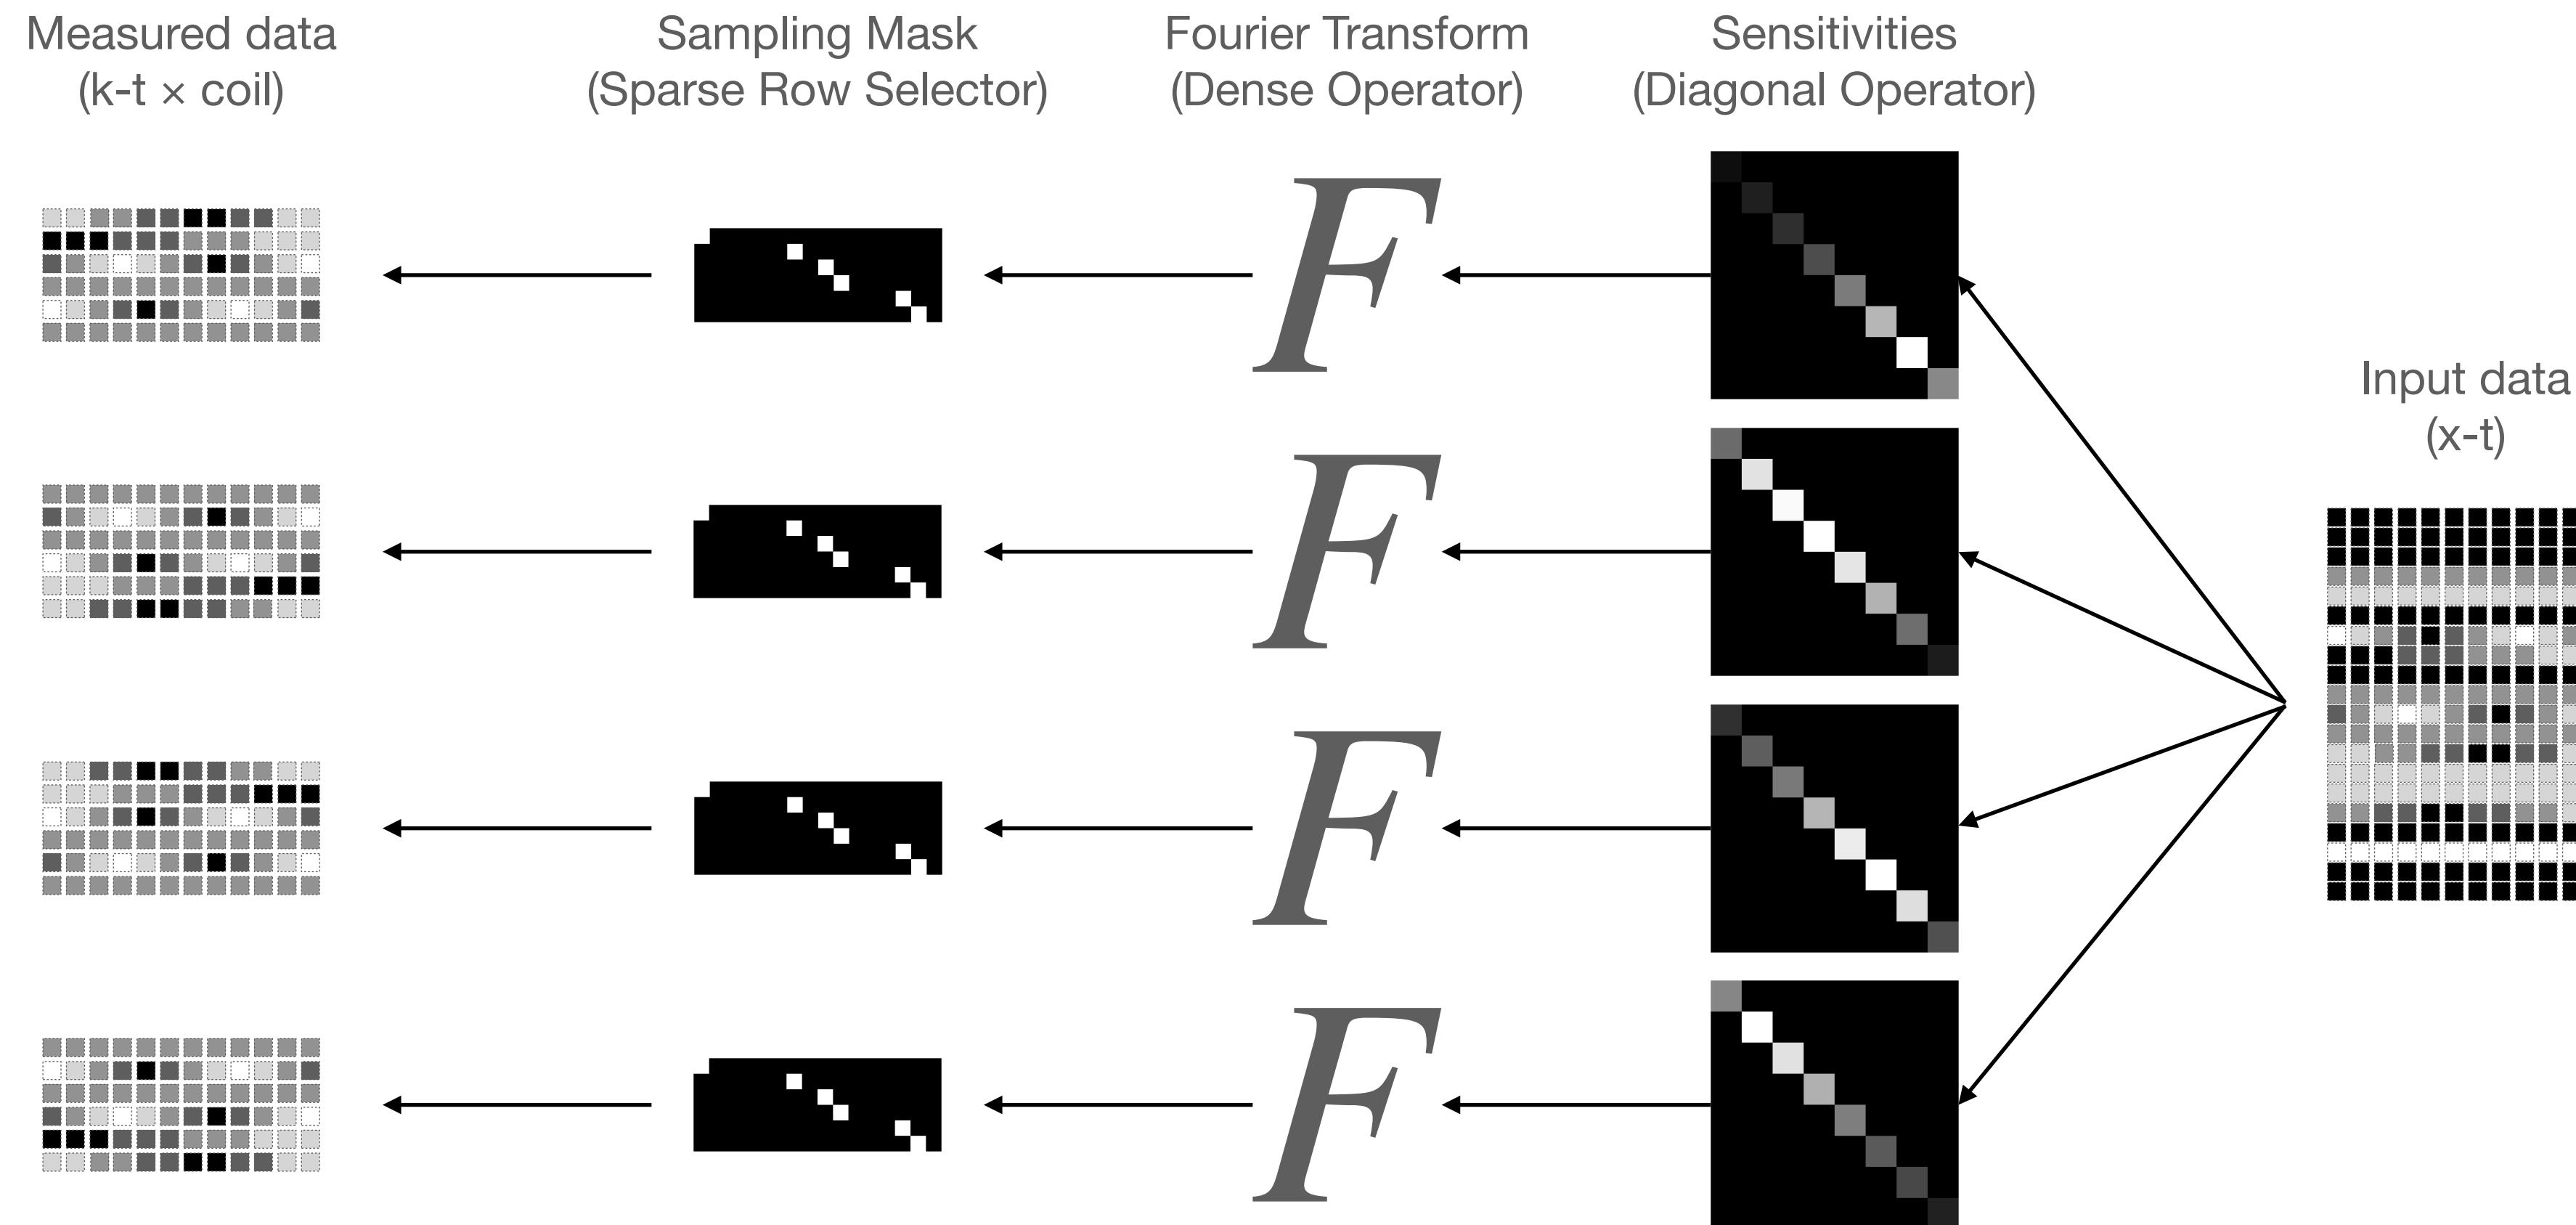

2. Construct the Forward Operator

Maps your “image” to the sampled k-space measurements

2. Construct the Forward Operator

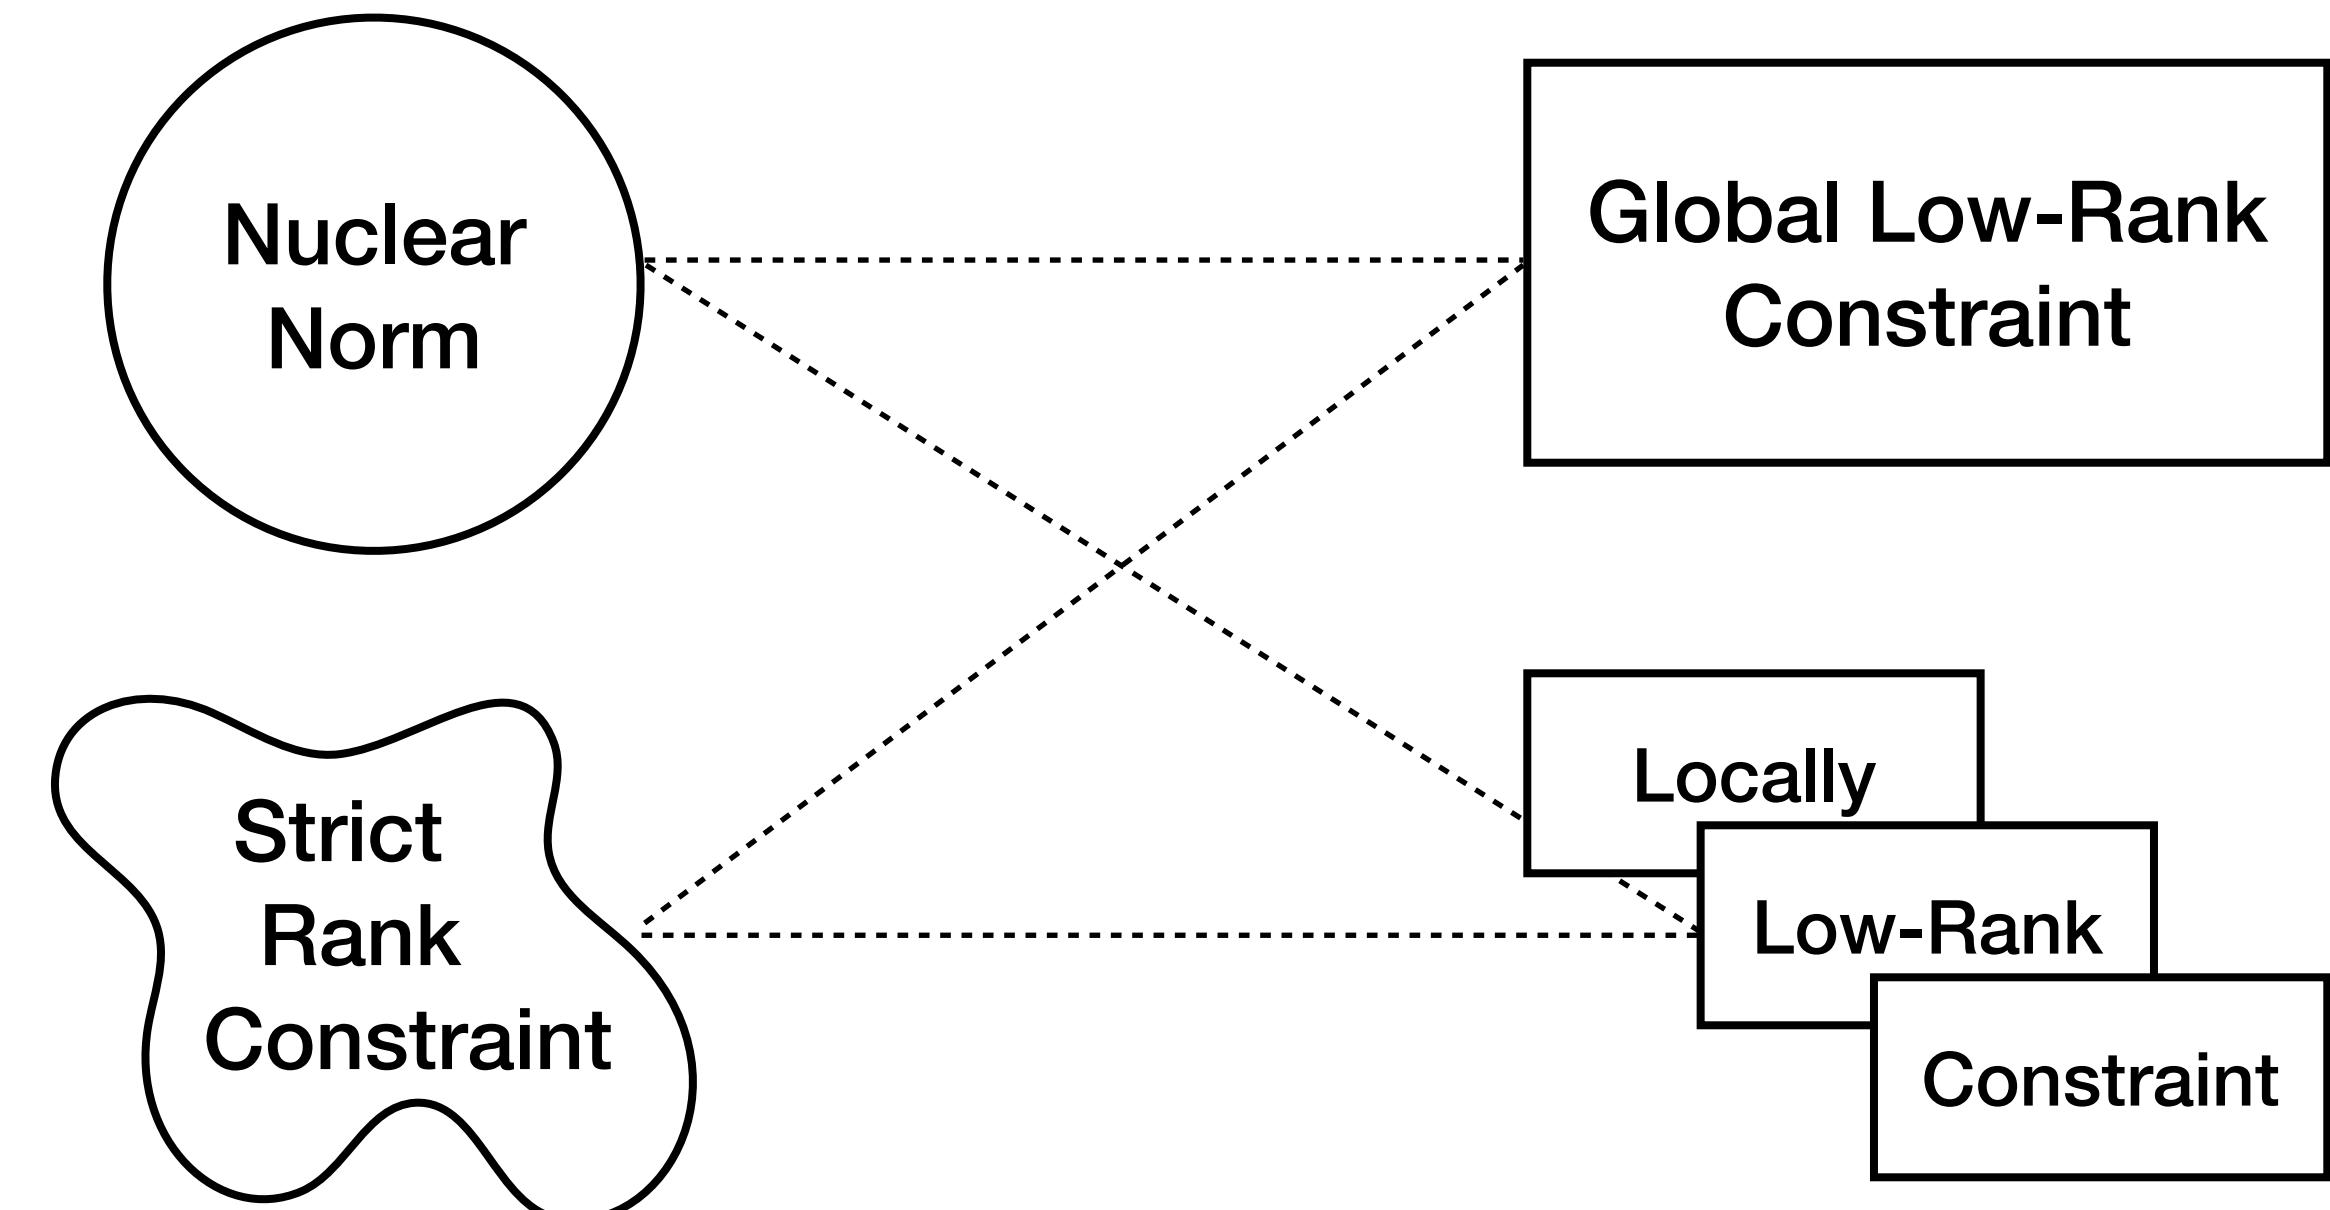

Maps your “image” to the sampled k-space measurements

3. Choose a Low-Rank Constraint

How will the low-rank constraint be enforced?

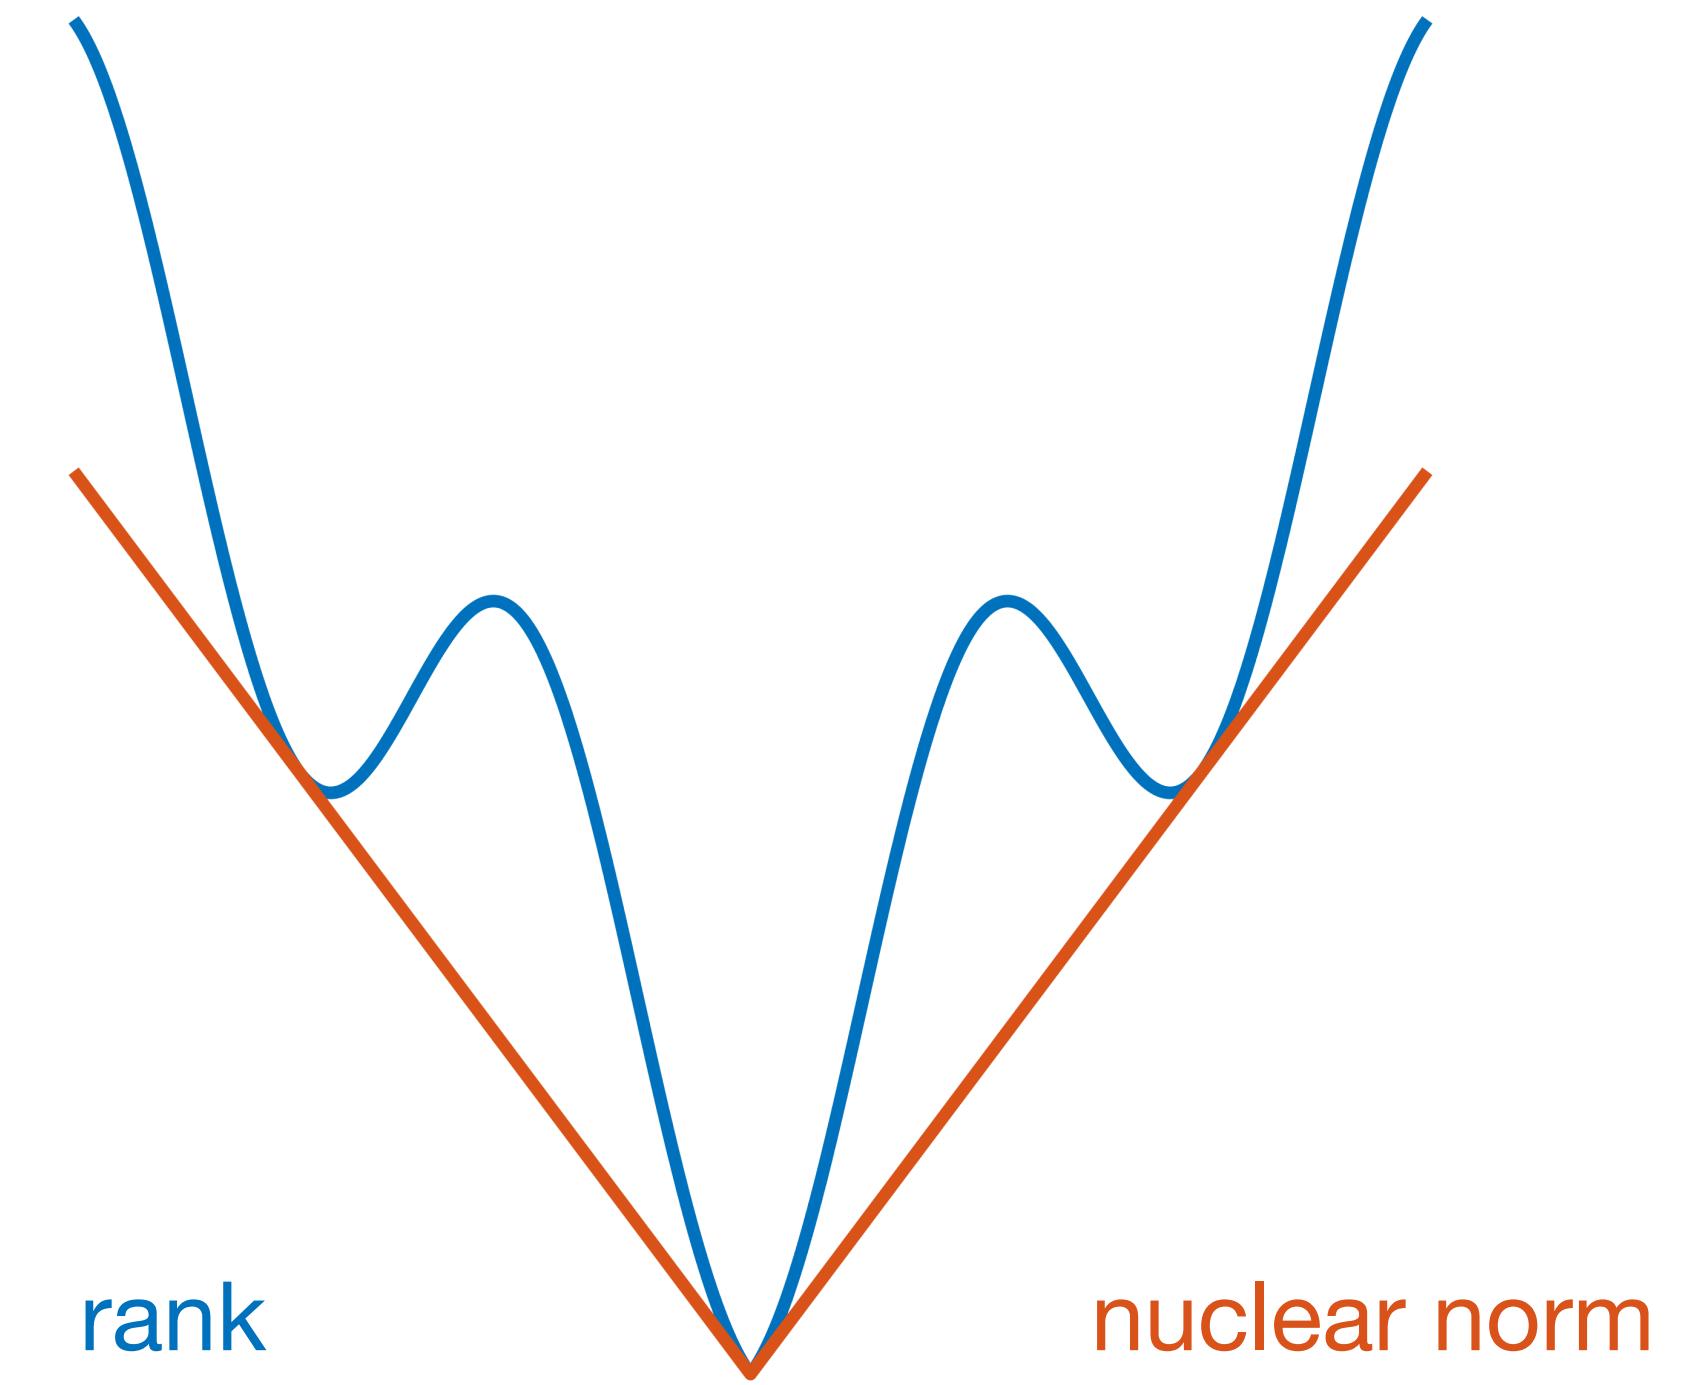

- Convex Nuclear Norm
 - Sum of singular values (analogous to L1)
- Non-Convex rank constraint
 - Matrix has exactly (or at most) rank “ r ”
- Global Low-Rank constraint
 - Entire matrix is low-rank
- Locally low-rank constraint
 - Matrix is “patch-wise” low-rank

3. Choose a Low-Rank Constraint

Nuclear Norm (Convex)

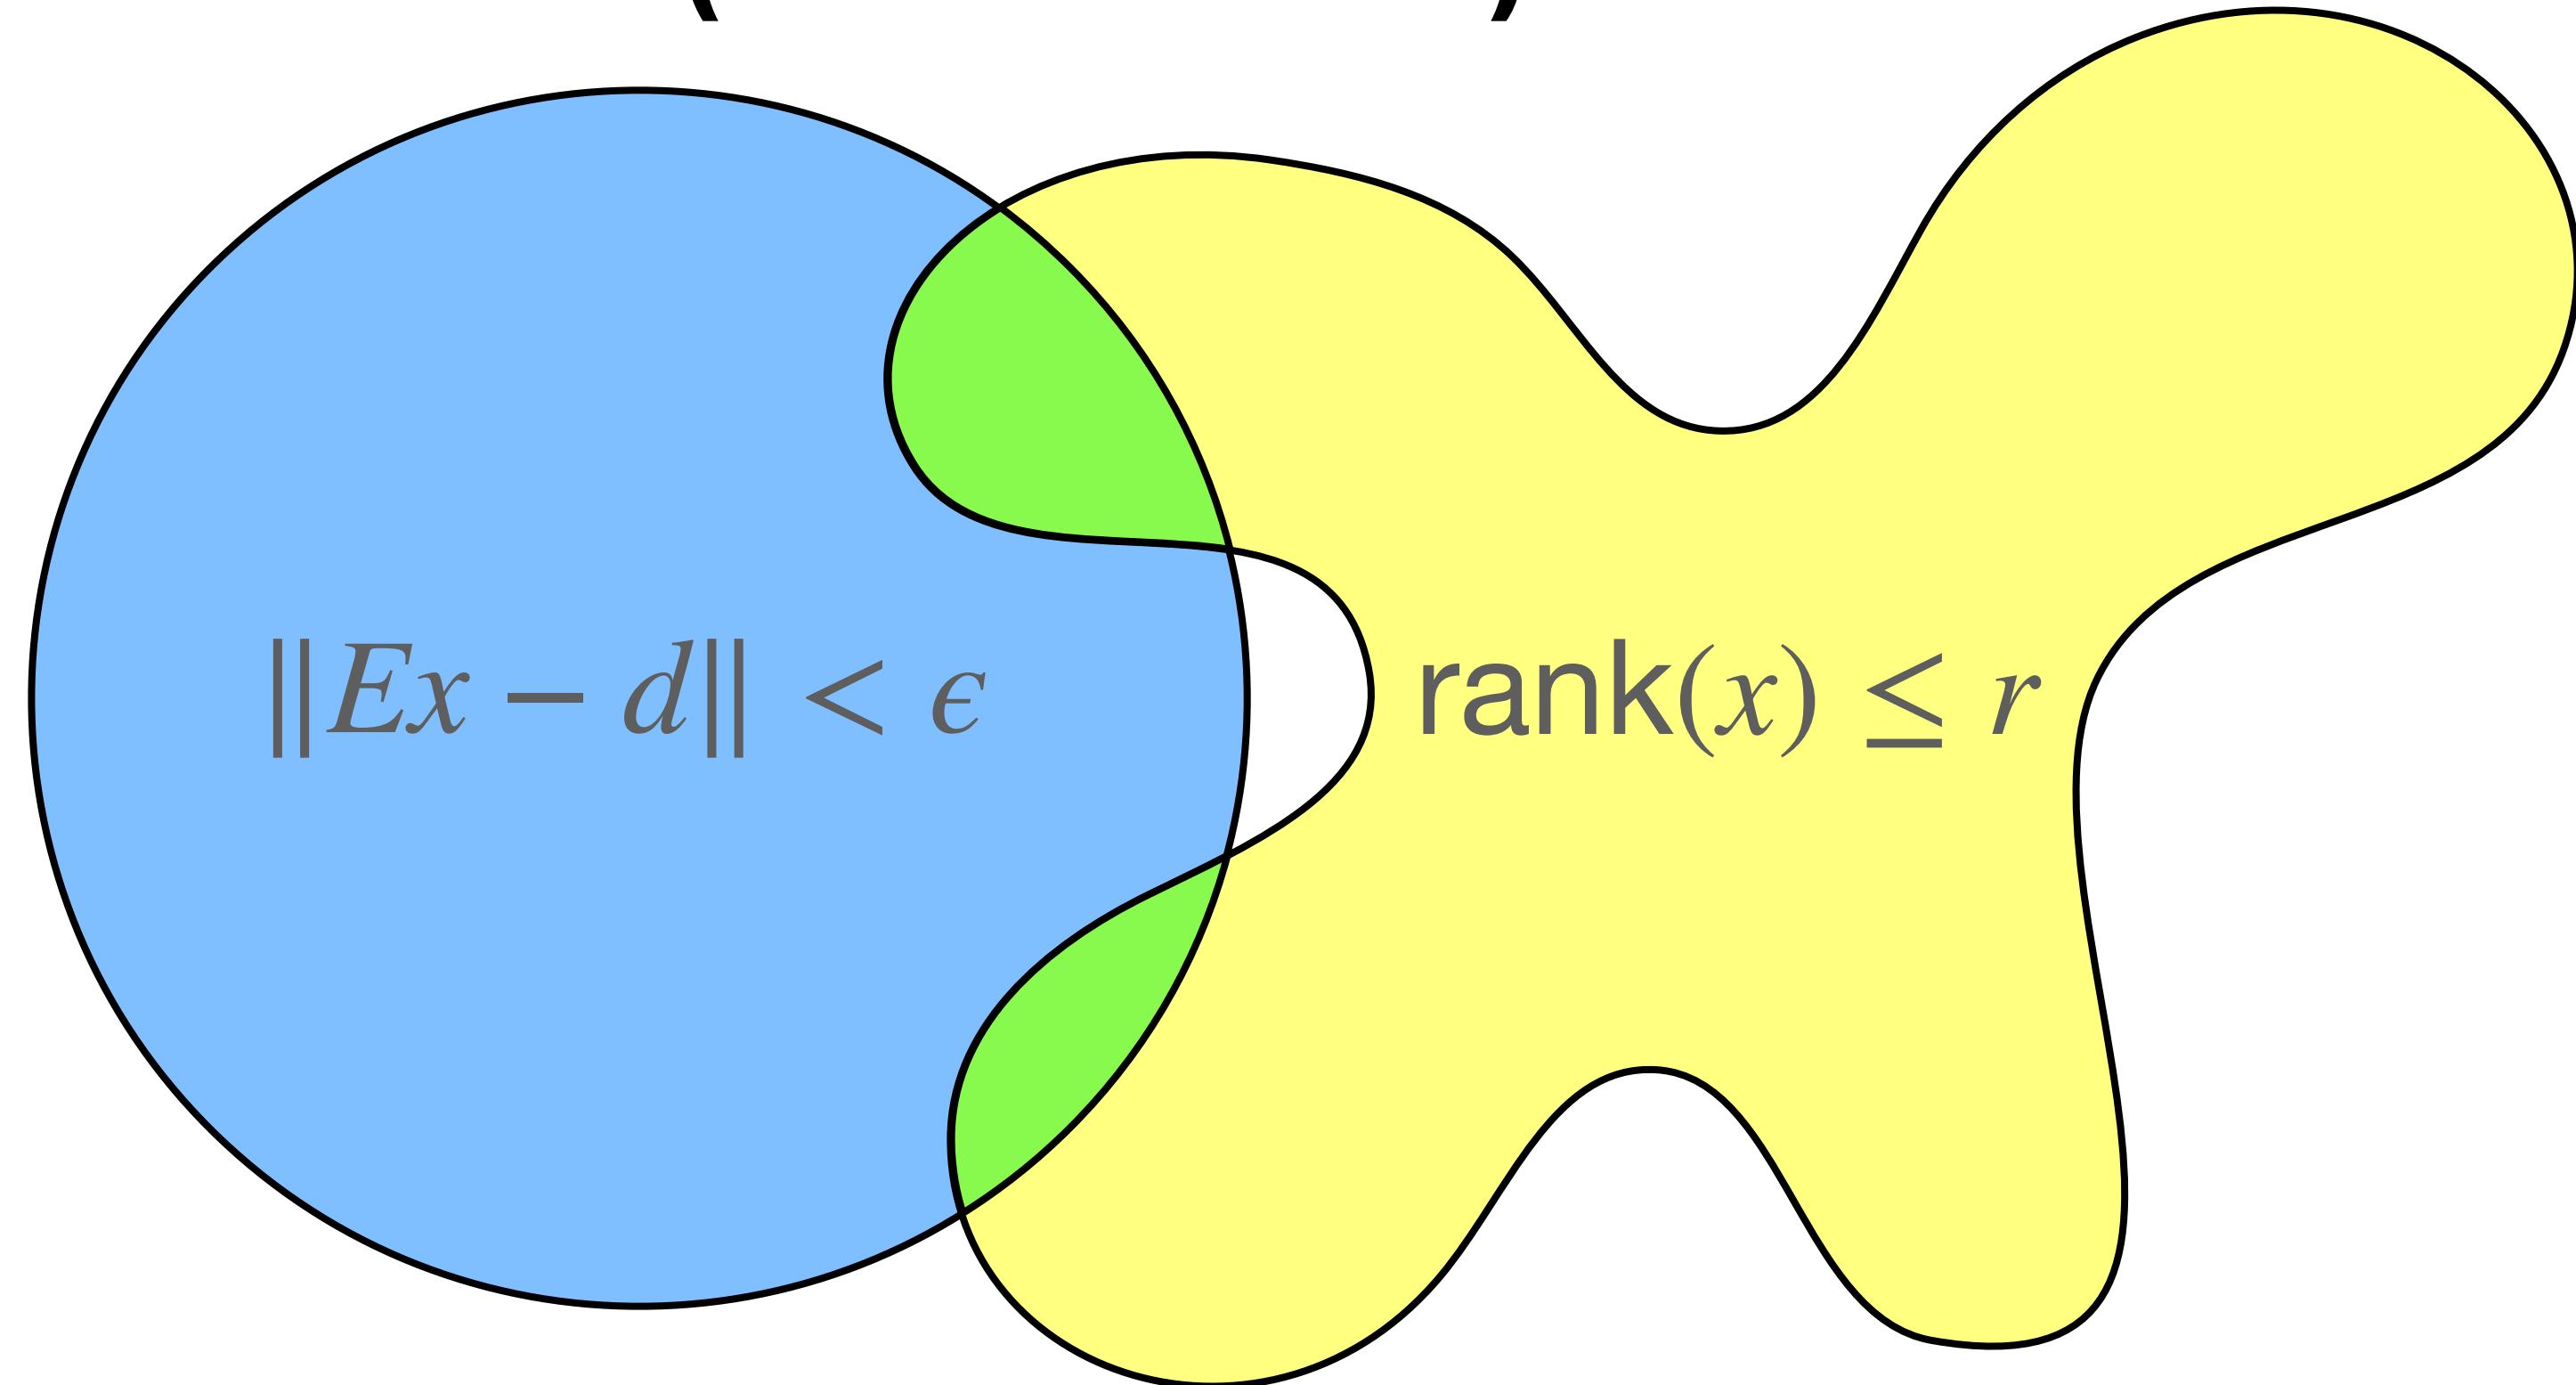

$$\|x\|_* = \left\| \begin{array}{c} \text{matrix with highlighted entries} \\ \text{with a diagonal line through them} \end{array} \right\|_1 = \sum_i \sigma_i$$

$$\min_x \|Ex - d\| + \lambda \|x\|_*$$

3. Choose a Low-Rank Constraint

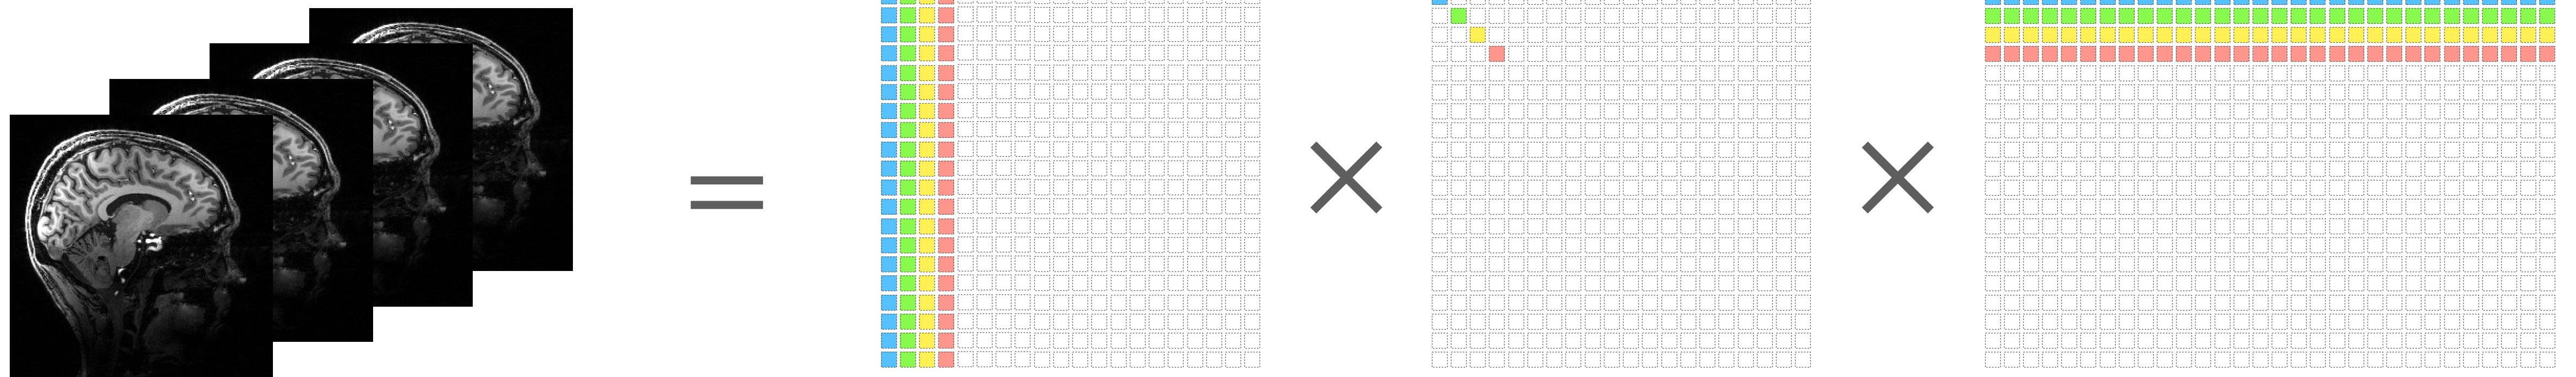

Strict Rank Constraint (Non-Convex)

$$\min_{\text{rank}(x) \leq r} \|Ex - d\|$$

3. Choose a Low-Rank Constraint

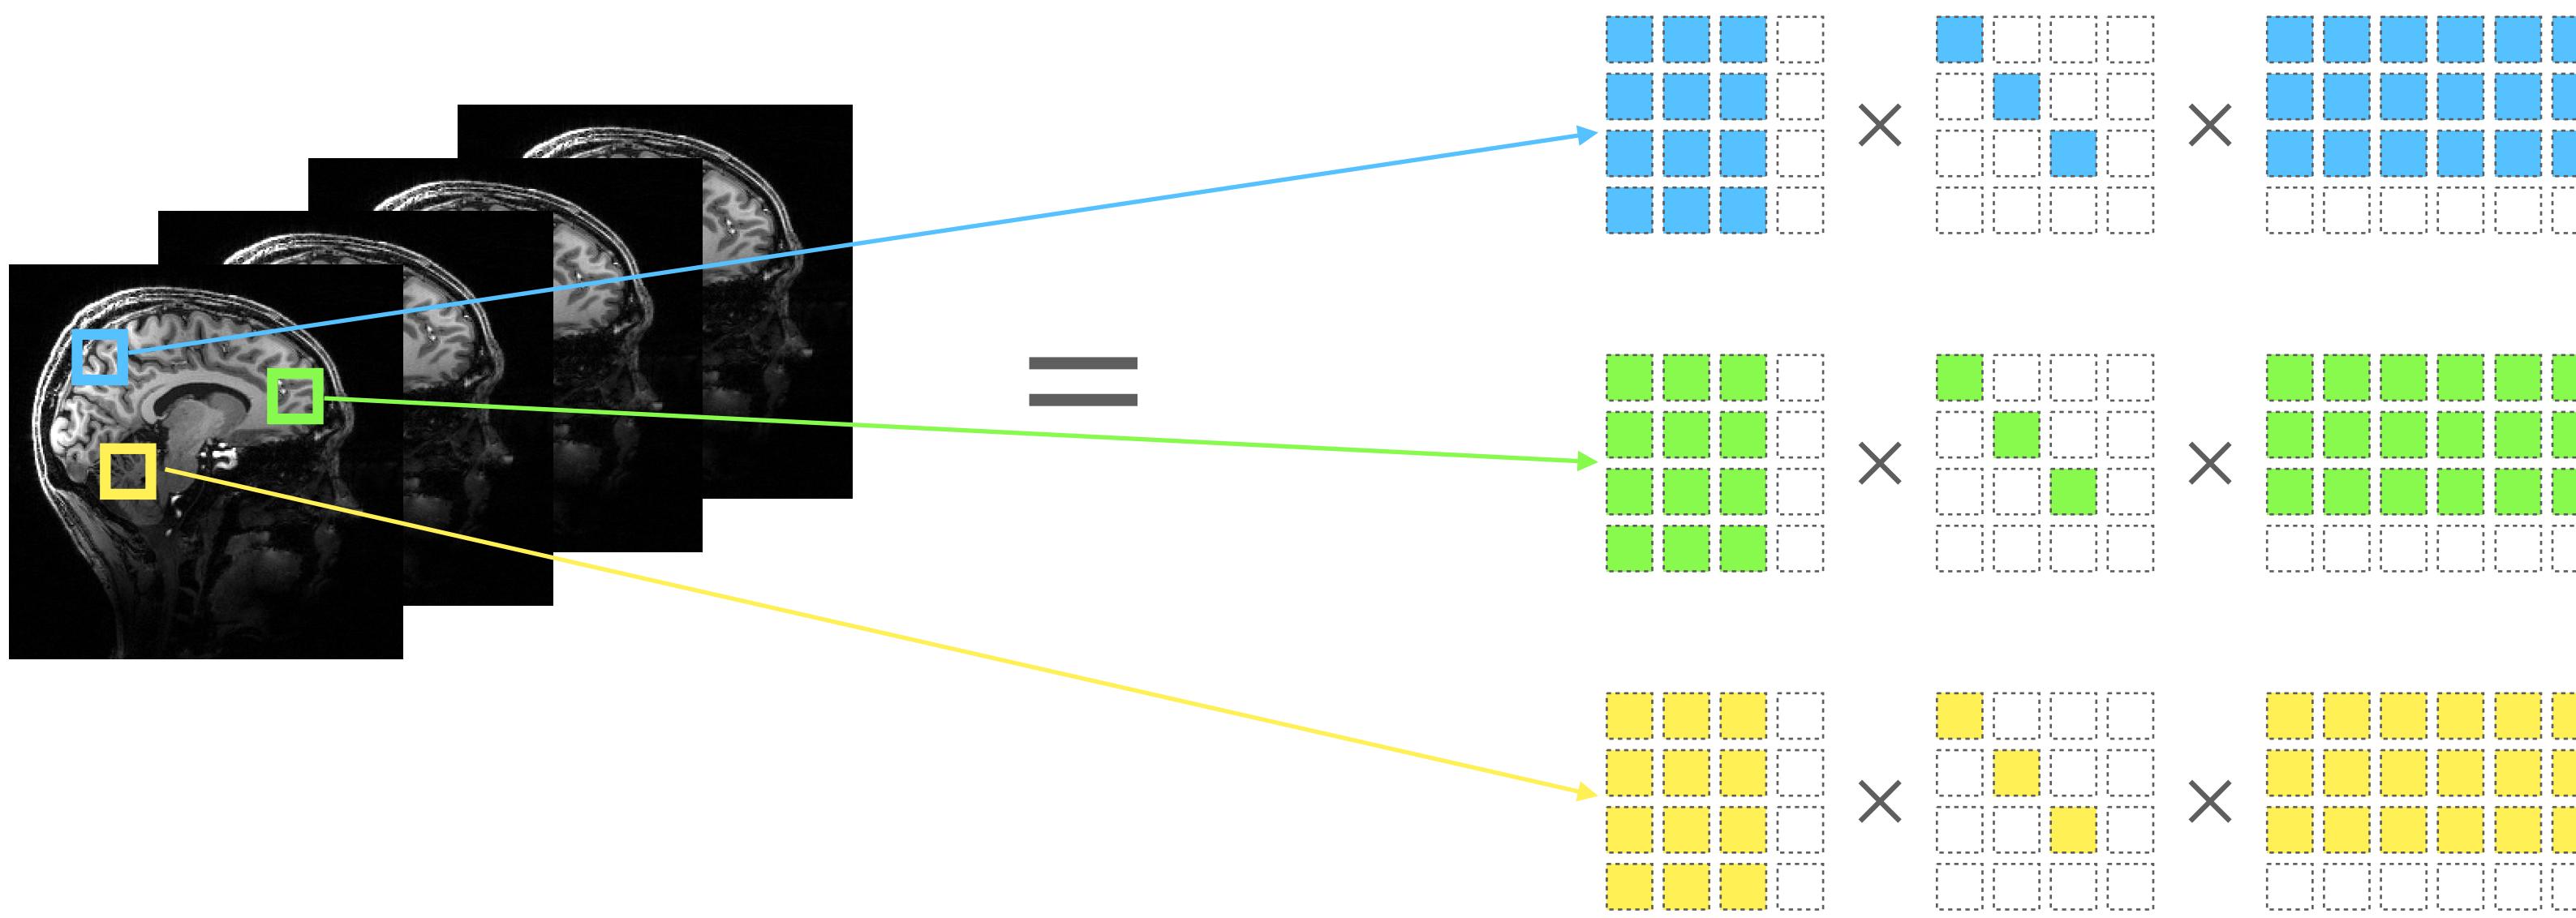

Global Low-Rank Constraint

$$\min_x \|Ex - d\| + \lambda \|x\|_*$$

3. Choose a Low-Rank Constraint

Locally Low-Rank Constraint

$$\min_x \|Ex - d\| + \lambda \sum_p \|R_p x\|_*$$

3. Choose a Low-Rank Constraint Extensions with other constraints or formulations

Low Rank + Sparse Decomposition¹

$$\min_{L,S} \|E(L + S) - d\| + \lambda_L \|L\|_* + \lambda_S \|\Psi S\|_1$$

Low Rank & Sparse Penalties²

$$\min_x \|Ex - d\| + \lambda_L \|x\|_* + \lambda_S \|\Psi x\|_1$$

Low Rank Tensor Reconstruction³

$$\min_x \|Ex - d\| + \lambda \sum_i \|x_{(i)}\|_*$$

3. Trzasko & Manduca, “A Unified Tensor Regression Framework for Calibrationless Dynamic, Multi-Channel MRI Reconstruction” ISMRM 2013

4. Algorithm

Optimize the cost function with some algorithm

- SVD-free: e.g. Matrix Factorization
- SVD-based: e.g. Proximal gradient method (Singular Value Thresholding)

4. Algorithm

Matrix Factorization - Low Rank by Construction

$$\min_{\substack{U \in \mathbb{C}^{m \times r} \\ V \in \mathbb{C}^{n \times r}}} \|E(UV^H) - d\|$$

$$U_{k+1} = \arg \min_U \|E(UV_k^H) - d\|_F$$

$$V_{k+1} = \arg \min_V \|E(U_{k+1}V^H) - d\|_F$$

Haldar & Hernando, "Rank-Constrained Solutions to Linear Matrix Equations Using PowerFactorization" IEEE Sig Proc Lett 2009

4. Algorithm

Matrix Factorization - Training data

$$\min_{U \in \mathbb{C}^{m \times r}} \|E(UV^H) - d\|$$

- V can be determined from training data
- e.g. low-resolution, fully-sampled k-space to estimate temporal basis vectors

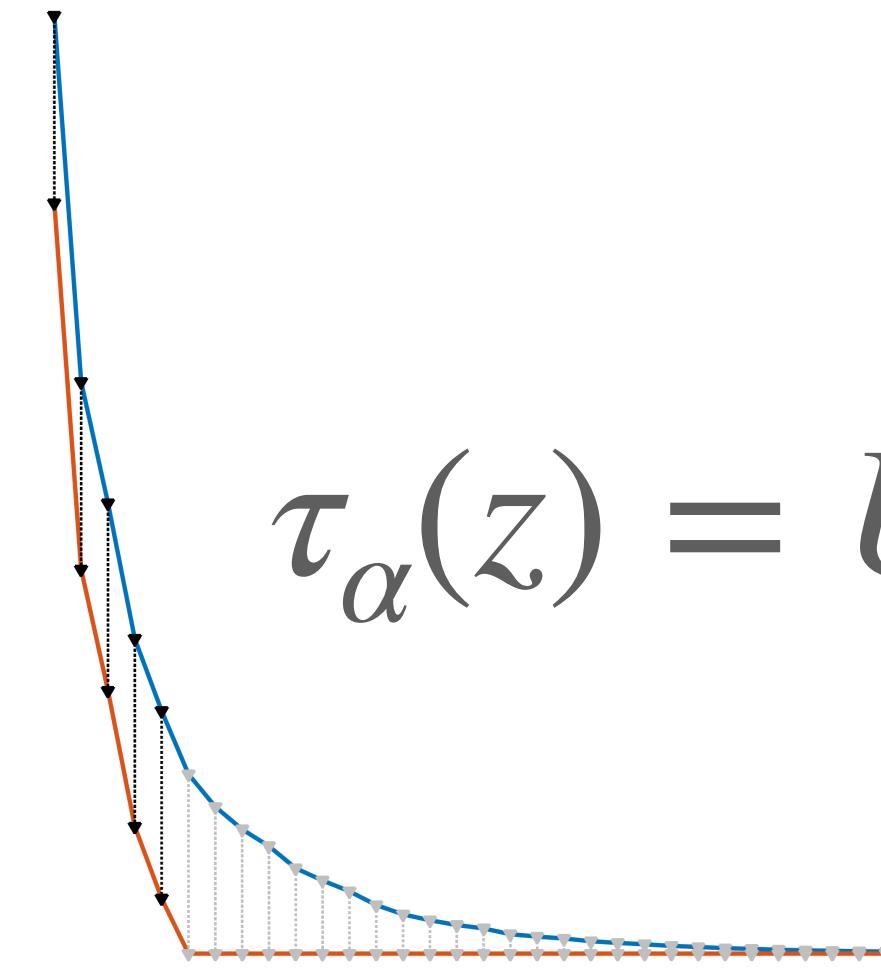

4. Algorithm

SVD-based thresholding

- Analogous to soft-thresholding algorithms for sparse reconstruction problems
- e.g. Alternating between gradient step w.r.t. data consistency and a singular value soft thresholding proximal projection step to promote low-rankness

$$y_{k+1} = x_k + \mu E^H(Ex_k - d)$$

$$x_{k+1} = \tau_{\lambda\mu}(y_{k+1})$$

$$\tau_\alpha(z) = U \cdot \max(\Sigma - \alpha, 0) \cdot V^H$$

Other Considerations

Sampling and Parameter Selection

- Sampling
 - With training data (e.g. low-resolution fully-sampled reference), under-sampling can be regular
 - Otherwise, typically more “random” or incoherent sampling, similar to compressed sensing
- Parameter Selection
 - Can be estimated from training data or other reference data, if available
 - Otherwise often empirically chosen, although model-order penalties can also be used

Structured Low-Rank Methods

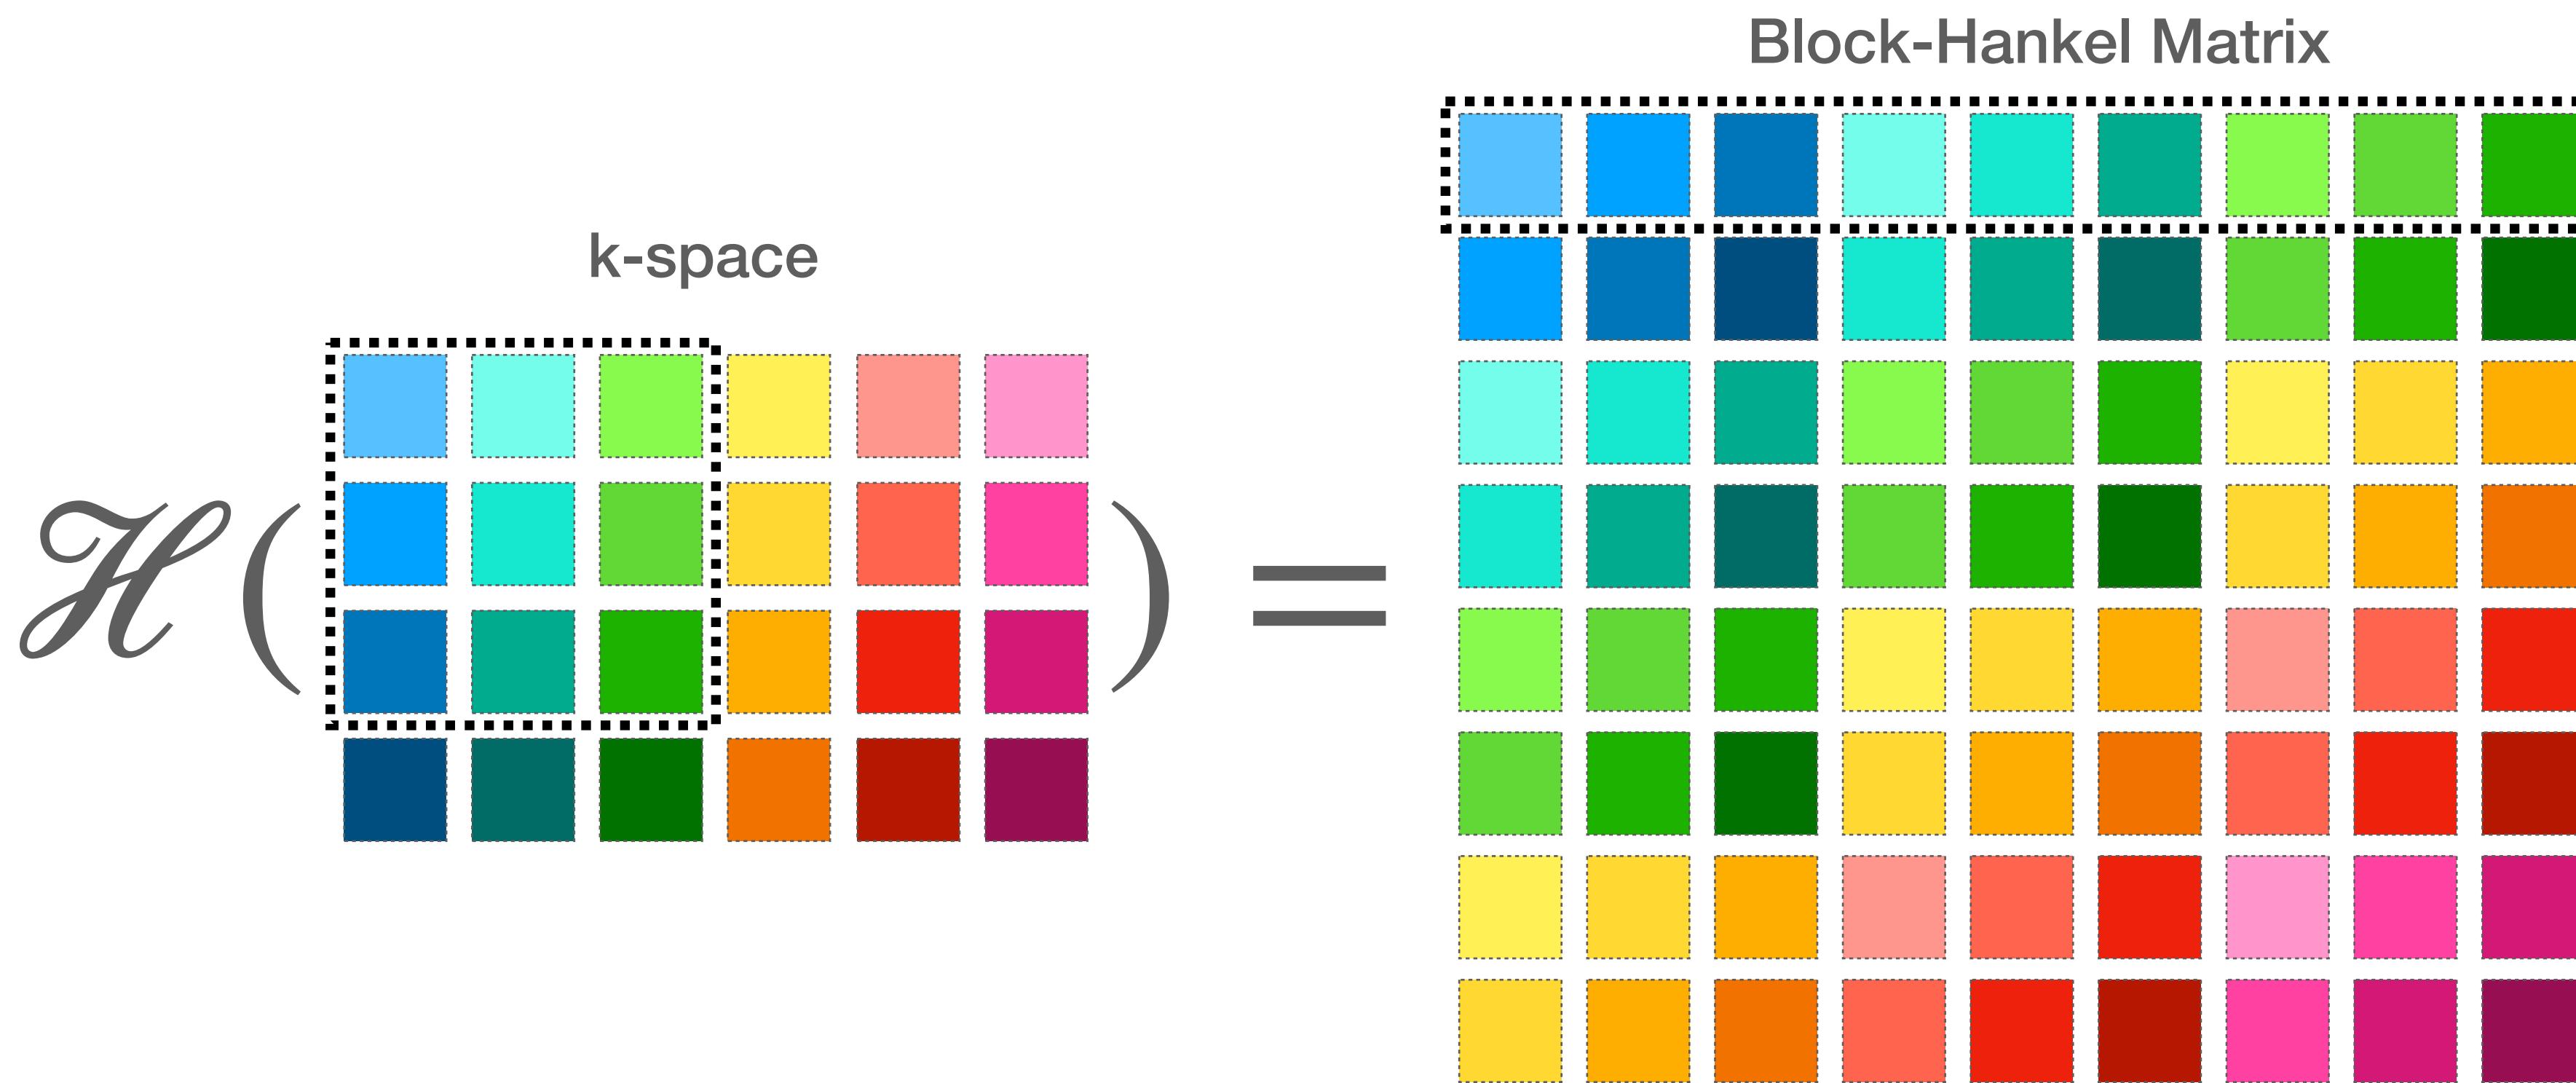

Structured Low Rank Methods

- Similar to general low-rank methods, but now it is not the data matrix *itself* that is low-rank, but rather a transformation of the input data
- Don't require multi-dimensional data, you can generate a structured low-rank matrix from a single image
- Typically involves collecting points of k-space using a kernel and concatenating them to form a Hankel structured matrix

Structured Low Rank Methods

The Hankel Matrix

- Take small windows or kernels and unravel them into vectors

Structured Low Rank Methods

The Hankel Matrix

- Take small windows or kernels and unravel them into vectors

Structured Low Rank Methods

The Hankel Matrix

- Stack, or concatenate the vectorized kernels

Block-Hankel Matrix

k-space

$$\mathcal{H} \left(\begin{array}{c|c|c|c|c|c} \text{light blue} & \text{light green} & \text{light red} & \text{light yellow} & \text{light pink} & \text{pink} \\ \text{blue} & \text{cyan} & \text{green} & \text{yellow} & \text{red} & \text{magenta} \\ \text{dark blue} & \text{dark cyan} & \text{dark green} & \text{orange} & \text{brown} & \text{purple} \\ \text{dark dark blue} & \text{dark dark cyan} & \text{dark dark green} & \text{light orange} & \text{light brown} & \text{light purple} \end{array} \right) = \begin{array}{ccccccccccccc} \text{light blue} & \text{light green} & \text{light red} & \text{light yellow} & \text{light pink} & \text{pink} & \text{light blue} & \text{light green} & \text{light red} & \text{light yellow} & \text{light pink} & \text{pink} & \text{light blue} & \text{light green} & \text{light red} \\ \text{blue} & \text{cyan} & \text{green} & \text{yellow} & \text{red} & \text{magenta} & \text{blue} & \text{cyan} & \text{green} & \text{yellow} & \text{red} & \text{magenta} & \text{blue} & \text{cyan} & \text{green} \\ \text{dark blue} & \text{dark cyan} & \text{dark green} & \text{orange} & \text{brown} & \text{purple} & \text{dark blue} & \text{dark cyan} & \text{dark green} & \text{orange} & \text{brown} & \text{purple} & \text{dark blue} & \text{dark cyan} & \text{dark green} \\ \text{dark dark blue} & \text{dark dark cyan} & \text{dark dark green} & \text{light orange} & \text{light brown} & \text{light purple} & \text{dark dark blue} & \text{dark dark cyan} & \text{dark dark green} & \text{light orange} & \text{light brown} & \text{light purple} & \text{dark dark blue} & \text{dark dark cyan} & \text{dark dark green} \\ \text{dark dark dark blue} & \text{dark dark dark cyan} & \text{dark dark dark green} & \text{light light orange} & \text{light light brown} & \text{light light purple} & \text{dark dark dark blue} & \text{dark dark dark cyan} & \text{dark dark dark green} & \text{light light orange} & \text{light light brown} & \text{light light purple} & \text{dark dark dark blue} & \text{dark dark dark cyan} & \text{dark dark dark green} \end{array}$$

$$\mathcal{H} \left(\begin{array}{cccccc} \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} \\ \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} \\ \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} \\ \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} \\ \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} \\ \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} & \text{[Color]} \end{array} \right) = \text{Block-Hankel Matrix}$$

The diagram illustrates the construction of a Block-Hankel Matrix from k-space data. On the left, a 6x6 grid labeled "k-space" contains 36 colored blocks. The colors form a repeating pattern of six distinct colors in a 3x6 grid. An equals sign follows the grid. To the right is a 12x12 grid labeled "Block-Hankel Matrix". This matrix is composed of 144 smaller 2x3 submatrices, each corresponding to one of the 36 blocks in the k-space grid. The submatrices are highlighted with dashed borders. The colors in the submatrices follow the same repeating pattern as the k-space grid.

$$x \circledast y = \mathcal{H}(x) y$$

Structured Low Rank Methods

Limited Support Intuition

Haldar, "Low-Rank Modeling of Local k -Space Neighborhoods (LORAKS) for Constrained MRI" IEEE-TMI 2014

Structured Low Rank Methods

Limited Support Intuition

$$A \times w - A = 0$$

Implies the Hankel-structured matrix $\mathcal{H}(\mathcal{F}[A])$ has a non-trivial null-space

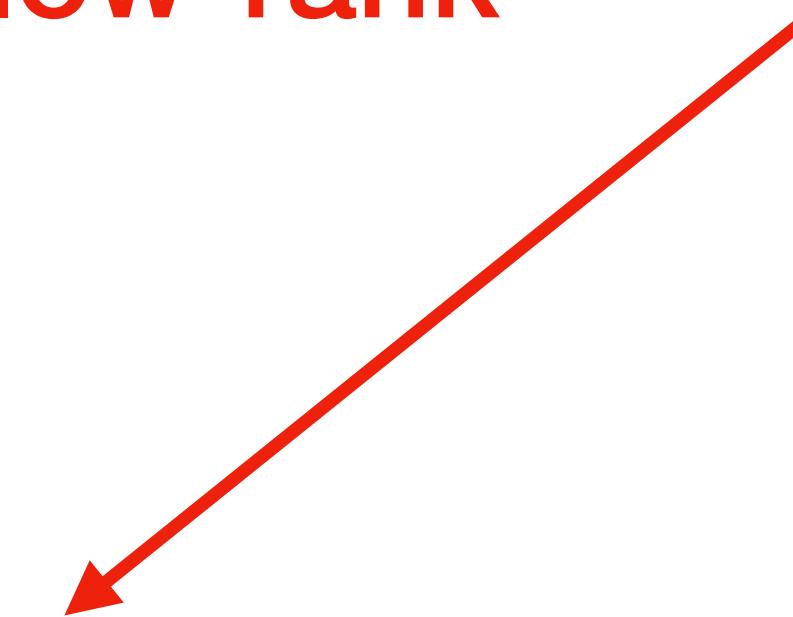

$$A \times (w - 1) = 0$$

Which in turn means that $\mathcal{H}(\mathcal{F}[A])$ has low-rank

$$A \times \tilde{w} = 0$$

$$\mathcal{F}[A] \circledast \mathcal{F}[\tilde{w}] = 0$$

$$\mathcal{H}(\mathcal{F}[A]) \cdot \text{vec}(\mathcal{F}[\tilde{w}]) = 0$$
